annotation class marker\n\n\n/**\n * Gives a declaration (a function, a property or a class) specific name in\n
JavaScript.\n *\n * This may be useful in the following cases:\n *\n * * There are two functions for which the

```

compiler gives same name in JavaScript, you can mark one with `@JsName(...)` to prevent the compiler from reporting error. You are writing a JavaScript library in Kotlin. The compiler produces mangled names for functions with parameters, which is unnatural for usual JavaScript developer. You can put `@JsName(...)` on functions you want to be available from JavaScript. For some reason you want to rename declaration, e.g. there's common term in JavaScript for a concept provided by the declaration, which is uncommon in Kotlin. Example:

```
kotlin
class Person(val name: String) {
    fun hello() {
        println("Hello $name!")
    }
}
@JsName("helloWithGreeting") fun hello(greeting: String) {
    println("$greeting $name!")
}
```

It's required to denote a valid JavaScript identifier. `@Retention(AnnotationRetention.BINARY)` `@Target(CLASS, FUNCTION, PROPERTY, CONSTRUCTOR, PROPERTY_GETTER, PROPERTY_SETTER)` public actual annotation class `JsName(actual val name: String)` Denotes an `external` declaration that must be imported from native JavaScript library. The compiler produces the code relevant for the target module system, for example, in case of `CommonJS`, it will import the declaration via the `require(...)` function. The annotation can be used on top-level external declarations (classes, properties, functions) and files. In case of file (which can't be `external`) the following rule applies: all the declarations in the file must be `external`. By applying `@JsModule(...)` on a file you tell the compiler to import a JavaScript object that contain all the declarations from the file. Example:

```
kotlin
@JsModule("jquery")
external abstract class JQuery() {
    // some declarations here
}
@JsModule("jquery")
external fun JQuery(element: Element): JQuery
```

It is not interpreted by the Kotlin compiler, it's passed as is directly to the target module system. `@see JsNonModule` `@Retention(AnnotationRetention.BINARY)` `@Target(CLASS, PROPERTY, FUNCTION, FILE)` public annotation class `JsModule(val import: String)` Denotes an `external` declaration that can be used without module system. By default, an `external` declaration is available regardless your target module system. However, by applying `[JsModule]` annotation you can make a declaration unavailable to `plain` module system. Some JavaScript libraries are distributed both as a standalone downloadable piece of JavaScript and as a module available as an npm package. To tell the Kotlin compiler to accept both cases, you can augment `[JsModule]` with the `@JsNonModule` annotation. For example:

```
kotlin
@JsModule("jquery")
@JsNonModule
@JsName("$")
external abstract class JQuery() {
    // some declarations here
}
@JsModule("jquery")
@JsNonModule
@JsName("$")
external fun JQuery(element: Element): JQuery
```

`@see JsModule` `@Retention(AnnotationRetention.BINARY)` `@Target(CLASS, PROPERTY, FUNCTION, FILE)` public annotation class `JsNonModule` Adds prefix to `external` declarations in a source file. JavaScript does not have concept of packages (namespaces). They are usually emulated by nested objects. The compiler turns references to `external` declarations either to plain unprefix names (in case of `plain` modules) or to plain imports. However, if a JavaScript library provides its declarations in packages, you won't be satisfied with this. You can tell the compiler to generate additional prefix before references to `external` declarations using the `@JsQualifier(...)` annotation. Note that a file marked with the `@JsQualifier(...)` annotation can't contain non-`external` declarations. Example:

```
@file:JsQualifier("my.jsPackageName")
package some.kotlinPackage
external fun foo(x: Int)
external fun bar(): String
```

It must be a sequence of valid JavaScript identifiers separated by the `.`` character. Examples of valid qualifiers are: `foo`, `bar.Baz`, `_.$.f`. `@see JsModule` `@Retention(AnnotationRetention.BINARY)` `@Target(AnnotationTarget.FILE)` public annotation class `JsQualifier(val value: String)` Exports top-level declaration on JS platform. Compiled module exposes declarations that are marked with this annotation without name mangling. This annotation can be applied to either files or top-level declarations. It is currently prohibited

to export the following kinds of declarations:

- * expect declarations
- * inline functions with reified type parameters
- * suspend functions
- * secondary constructors without `@JsName`
- * extension properties
- * enum classes
- * annotation classes

Signatures of exported declarations must only contain "exportable" types:

- * `dynamic`, `Any`, `String`, `Boolean`, `Byte`, `Short`, `Int`, `Float`, `Double`
- * `BooleanArray`, `ByteArray`, `ShortArray`, `IntArray`, `FloatArray`, `DoubleArray`
- * `Array<exportable-type>`
- * Function types with exportable parameters and return types
- * `external` or `@JsExport` classes and interfaces
- * Nullable counterparts of types above
- * Unit return type. Must not be nullable

This annotation is experimental, meaning that restrictions mentioned above are subject to change.

parameter or\n * extensions for that type. The extensions must be themselves annotated with `@BuilderInference`. \n
*\n * Example: we declare\n * ```\n * fun <T> sequence(@BuilderInference block: suspend SequenceScope<T>.() -

the type argument of the resulting sequence is inferred to `String` from\n * the argument of the

type of the value returned from\n * the lambda function passed to this functional parameter.\n * \n * Example:\n *

create(doubleProducer: () -> Double): Double\n * \n * val newValue = create { 3.14 } \n * ```\n * \n * The annotation

 * Defines deep recursive function that keeps its stack on the heap,
 * which allows very deep recursive computations that do not use the actual call stack.
 * To initiate a call to this deep recursive function use its [invoke] function.
 * As a rule of thumb, it should be used if recursion goes deeper than a thousand calls.
 * The [DeepRecursiveFunction] takes one parameter of type [T] and returns a result of type [R].
 * The [block] of code defines the body of a recursive function. In this block
 * [callRecursive][DeepRecursiveScope.callRecursive] function can be used to make a recursive call
 * to the declared function. Other instances of [DeepRecursiveFunction] can be called
 * in this scope with `callRecursive` extension, too.
 * For example, take a look at the following recursive tree class and a deeply
 * recursive instance of this tree with 100K nodes:
 * class Tree(val left: Tree? = null, val right: Tree? = null) {

```

```

Tree(it) }.take(100_000).last())\n * ```\n *\n * A regular recursive function can be defined to compute a depth of a
tree:\n *\n * ```\n * fun depth(t: Tree?): Int =\n * if (t == null) 0 else max(depth(t.left), depth(t.right)) + 1\n *
println(depth(deepTree)) // StackOverflowError\n * ```\n *\n * If this `depth` function is called for a `deepTree` it
produces `StackOverflowError` because of deep recursion.\n * However, the `depth` function can be rewritten using
`DeepRecursiveFunction` in the following way, and then\n * it successfully computes
[depth(deepTree)][DeepRecursiveFunction.invoke] expression:\n *\n * ```\n * val depth =
DeepRecursiveFunction<Tree?, Int> { t ->\n * if (t == null) 0 else max(callRecursive(t.left),
callRecursive(t.right)) + 1\n * }\n * println(depth(deepTree)) // Ok\n * ```\n *\n * Deep recursive functions can also
mutually call each other using a heap for the stack via\n * [callRecursive][DeepRecursiveScope.callRecursive]
extension. For example, the\n * following pair of mutually recursive functions computes the number of tree nodes at
even depth in the tree.\n *\n * ```\n * val mutualRecursion = object {\n * val even:
DeepRecursiveFunction<Tree?, Int> = DeepRecursiveFunction { t ->\n * if (t == null) 0 else
odd.callRecursive(t.left) + odd.callRecursive(t.right) + 1\n * }\n * val odd: DeepRecursiveFunction<Tree?,
Int> = DeepRecursiveFunction { t ->\n * if (t == null) 0 else even.callRecursive(t.left) +
even.callRecursive(t.right)\n * }\n * }\n * ```\n *\n * @param [T] the function parameter type.\n * @param [R] the function result type.\n * @param block the function
body.\n * ^\n * @SinceKotlin("1.7")\n * @WasExperimental(ExperimentalStdlibApi::class)\n * public class
