\* Parameter decorator to be used on constructor parameters, which tells the DI framework to start dependency resolution from the parent injector. Resolution works upward through the injector hierarchy, so the local injector is not checked for a provider.

`@usageNotes` In the following example, the dependency can be resolved when instantiating a child, but not when instantiating the class itself.

```

<code-example path="core/di/ts/metadata_spec.ts" region="SkipSelf">
@see [Dependency Injection guide](guide/dependency-injection-in-action#skip).
@see `Self`
@see `Optional`
() : any;
new(): SkipSelf;
}
Type of the `SkipSelf` metadata.
@publicApi
export interface SkipSelf {
 `SkipSelf` decorator and metadata.
 @Annotation
 @publicApi
 export const SkipSelf: SkipSelfDecorator = makeParamDecorator('SkipSelf');
 Type of the `Host` decorator / constructor function.
 @publicApi
 export interface HostDecorator {
 Parameter decorator on a view-provider parameter of a class constructor that tells the DI framework to resolve the view by checking injectors of child elements, and stop when reaching the host element of the current component.
 @usageNotes
 The following shows use with the `@Optional` decorator, and allows for a null result.
 <code-example path="core/di/ts/metadata_spec.ts" region="Host">
 </code-example>
 For an extended example, see ["Dependency Injection Guide"](guide/dependency-injection-in-action#optional).
 () : any;
 new(): Host;
 }
 Type of the Host metadata.
 @publicApi
 export interface Host {
 }
 Host decorator and metadata.
 @Annotation
 @publicApi
 export const Host: HostDecorator = makeParamDecorator('Host');
 Type of the Attribute decorator / constructor function.
 @publicApi
 export interface AttributeDecorator {
 Parameter decorator for a directive constructor that designates a host-element attribute whose value is injected as a constant string literal.
 @usageNotes
 Suppose we have an `<input>` element and want to know its `type`.
 <code><input type="text"></code>
 The following example uses the decorator to inject the string literal `text` in a directive.
 { @example core/ts/metadata/metadata.ts region='attributeMetadata' }
 The following example uses the decorator in a component constructor.
 { @example core/ts/metadata/metadata.ts region='attributeFactory' }
 (name: string): any;
 new(name: string): Attribute;
 }
 Type of the Attribute metadata.
 @publicApi
 export interface Attribute {
 The name of the attribute whose value can be injected.
 attributeName: string;
 }
 Attribute decorator and metadata.
 @Annotation
 @publicApi
 export const Attribute: AttributeDecorator =
 makeParamDecorator('Attribute', (attributeName?: string) =>
 ({ attributeName }));
 }

At a minimum, this includes a `factory` which defines how to create the given type `T`, possibly\n * requesting
injection of other types if necessary.\n *\n * Optionally, a `providedIn` parameter specifies that the given type

```

belongs to a particular `InjectorDef`, `NgModule`, or a special scope (e.g. `'root'`). A value of `'null'` indicates that the injectable does not belong to any scope.

`@codeGenApi` `@publicApi` The ViewEngine compiler emits code with this type for injectables. This code is deployed to npm, and should be treated as public api.

```

export interface InjectableDef<T> {
 /** Specifies that the given type belongs to a particular injector:
 * - `InjectorType` such as `NgModule`,
 * - `root` the root injector
 * - `any` all injectors.
 * - `null`, does not belong to any injector. Must be explicitly listed in the injector
 * `providers`.
 */
 providedIn:
 InjectorType<any> | 'root' | 'platform' | 'any' | null;
 /** The token to which this definition belongs.
 * Note that this may not be the same as the type that the `factory` will create.
 */
 token: unknown;
 /** Factory method to execute to create an instance of the injectable.
 */
 factory: (t?: Type<any>) => T;
 /** In a case of no explicit injector, a location where the instance of the injectable is stored.
 */
 value: T | undefined;
}

```

Information about the providers to be included in an `Injector` as well as how the given type which carries the information should be created by the DI system. An `InjectorDef` can import other types which have `InjectorDefs`, forming a deep nested structure of providers with a defined priority (identically to how `NgModule`'s also have an import/dependency structure).

**NOTE:** This is a private type and should not be exported.

`@codeGenApi` `@publicApi` `@next` export interface `InjectorDef<T>` {  
`factory: () => T;`  
 // TODO(alxhub): Narrow down the type here once decorators properly change the return type of the  
 // class they are decorating (to add the prov property for example).  
`providers:`  
`(Type<any> | ValueProvider | ExistingProvider | FactoryProvider | ConstructorProvider |`  
`StaticClassProvider | ClassProvider | any[])[];`  
`imports:`  
`(InjectorType<any> | InjectorTypeWithProviders<any>);`  
}

A `Type` which has an `InjectableDef` static field. `InjectableDefType`'s contain their own Dependency Injection metadata and are usable in an `InjectorDef`-based `StaticInjector`.

`@publicApi` `@next` export interface `InjectableType<T>` extends `Type<T>` {  
 /\*\* Opaque type whose structure is highly version dependent. Do not rely on any properties.
 \*/
 prov: never;
}

A type which has an `InjectorDef` static field. `InjectorDefTypes` can be used to configure a `StaticInjector`.

`@publicApi` `@next` export interface `InjectorType<T>` extends `Type<T>` {  
 /\*\* Opaque type whose structure is highly version dependent. Do not rely on any properties.
 \*/
 inj: never;
}

Describes the `InjectorDef` equivalent of a `ModuleWithProviders`, an `InjectorDefType` with an associated array of providers. Objects of this type can be listed in the imports section of an `InjectorDef`.

**NOTE:** This is a private type and should not be exported.

`@next` export interface `InjectorTypeWithProviders<T>` {  
`ngModule: InjectorType<T>;`  
`providers?:`  
`(Type<any> | ValueProvider | ExistingProvider | FactoryProvider | ConstructorProvider |`  
`StaticClassProvider | ClassProvider | any[])[];`  
}

Construct an `InjectableDef` which defines how a token will be constructed by the DI system, and in which injectors (if any) it will be available. This should be assigned to a static `prov` field on a type, which will then be an `InjectableType`.

**Options:**  
`providedIn` determines which injectors will include the injectable, by either associating it with an @NgModule or other InjectorType, or by specifying that this injectable should be provided in the 'root' injector, which will be the application-level injector in most apps.  
factory` gives the zero argument function which will create an instance of the injectable. The factory can call inject to access the Injector and request injection of dependencies.  
@codeGenApi @publicApi This instruction has been emitted by ViewEngine for some time and is deployed to npm.  
@next export function defineInjectable<T>(opts: { token: unknown, providedIn?: Type<any> | 'root' | 'platform' | 'any' | null, factory: () => T, }): never {  
 return ({  
 token: opts.token,  
 providedIn: opts.providedIn as any | null,  
 factory: opts.factory,  
 value: undefined,  
 }) as InjectableDef<T> as never;
}`

`@deprecated` in v8, delete after v10. This API should be used only be generated code, and that code should now use `defineInjectable` instead.

`@publicApi` `@next` export const `defineInjectable = defineInjectable;`

Construct an `InjectorDef` which configures an injector. This should be assigned to a static injector def (`'inj'`) field on a type, which will then be an `InjectorType`.

**Options:**  
`factory` : an InjectorType is an instantiable type, so a zero argument factory` function to create the type must be provided. If that factory function needs to inject arguments, it`

can use the `inject` function.

`providers`: an optional array of providers to add to the injector. Each provider must either have a factory or point to a type which has a `prov` static property (the type must be an InjectableType`).`

`imports`: an optional array of imports of other `InjectorType`s or InjectorTypeWithModule`s` whose providers will also be added to the injector. Locally provided types will override providers from imports.`

`@codeGenApi`export function defineInjector(options: {factory: () => any, providers?: any[], imports?: any[]}): never {return ({factory: options.factory, providers: options.providers || [], imports: options.imports || [], } as InjectorDef<any>) as never;}`

`Read the injectable def (prov`) for type` in a way which is immune to accidentally reading inherited value.`

`@param type A type which may have its own (non-inherited) prov`.`

`export function getInjectableDef<T>(type: any): InjectableDef<T>|null {return getOwnDefinition(type, NG_PROV_DEF) || getOwnDefinition(type, NG_INJECTABLE_DEF);}`

`Return definition only if it is defined directly on type` and is not inherited from a base class of type`.`

`function getOwnDefinition<T>(type: any, field: string): InjectableDef<T>|null {return type.hasOwnProperty(field) ? type[field] : null;}`

`Read the injectable def (prov`) for type` or read the prov` from one of its ancestors.`

`@param type A type which may have prov`, via inheritance.`

`@deprecated Will be removed in a future version of Angular, where an error will occur in the scenario if we find the prov` on an ancestor only.`

`export function getInheritedInjectableDef<T>(type: any): InjectableDef<T>|null {const def = type && (type[NG_PROV_DEF] || type[NG_INJECTABLE_DEF]);if (def) {const typeName = getTypeName(type); // TODO(FW-1307): Re-add ngDevMode when closure can handle it // ngDevMode && console.warn(`DEPRECATED: DI is instantiating a token "${typeName}" that inherits its @Injectable decorator but does not provide one itself.` + `This will become an error in a future version of Angular. Please add @Injectable() to the "${typeName} typeName}`" class.);return def;} else {return null;}}`

`Gets the name of a type, accounting for some cross-browser differences.`

`function getTypeName(type: any): string { // `Function.prototype.name` behaves differently between IE and other browsers. In most browsers // it'll always return the name of the function itself, no matter how many other functions it // inherits from. On IE the function doesn't have its own `name` property, but it takes it from // the lowest level in the prototype chain. E.g. if we have `class Foo extends Parent` most // browsers will evaluate `Foo.name` to `Foo` while IE will return `Parent`. We work around // the issue by converting the function to a string and parsing its name out that way via a regex. if (type.hasOwnProperty('name')) {return type.name;} \n const match = (" + type).match(/^function\s*(\s*\[.+])? : match[1];}`

`Read the injector def type in a way which is immune to accidentally reading inherited value.`

`@param type type which may have an injector def (inj`)`

`export function getInjectorDef<T>(type: any): InjectorDef<T>|null {return type && (type.hasOwnProperty(NG_INJ_DEF) || type.hasOwnProperty(NG_INJECTOR_DEF)) ? (type as any)[NG_INJ_DEF] : null;}`

`export const NG_PROV_DEF = getClosureSafeProperty({prov: getClosureSafeProperty});`

`export const NG_INJ_DEF = getClosureSafeProperty({inj: getClosureSafeProperty});`

`We need to keep these around so we can read off old defs if new defs are unavailable`

`export const NG_INJECTABLE_DEF = getClosureSafeProperty({ngInjectableDef: getClosureSafeProperty});`

`export const NG_INJECTOR_DEF = getClosureSafeProperty({ngInjectorDef: getClosureSafeProperty});`

`","`

`@license` Copyright Google LLC All Rights Reserved.`

`Use of this source code is governed by an MIT-style license that can be found in the LICENSE file at https://angular.io/license`

`import {Type} from './interface/type';`

`import {assertLessThan} from './util/assert';`

`import {defineInjectable} from './interface/defs';`

`Creates a token that can be used in a DI Provider.`

`Use an InjectionToken` whenever the type you are injecting is not reified (does not have a runtime representation) such as when injecting an interface, callable type, array or parameterized type.`

`InjectionToken` is parameterized on T` which is the type of object which will be returned by the Injector`. This provides additional level of type safety.`

`interface MyInterface {...}`

`var myInterface = injector.get(new InjectionToken<MyInterface>('SomeToken'));`

`// myInterface is inferred to be MyInterface.`

`When creating an InjectionToken`, you can optionally specify a factory function which returns`

(possibly by creating) a default value of the parameterized type `T`. This sets up the `InjectionToken` using this factory as a provider as if it was defined explicitly in the application's root injector. If the factory function, which takes zero arguments, needs to inject dependencies, it can do so using the `inject` function. See below for an example. Additionally, if a `factory` is specified you can also specify the `providedIn` option, which overrides the above behavior and marks the token as belonging to a particular `NgModule`. As mentioned above, `root` is the default value for `providedIn`.

```

@usageNotes
Basic Example
Plain InjectionToken
@{example core/di/ts/injector_spec.ts region='InjectionToken'}
Tree-shakable InjectionToken
@{example core/di/ts/injector_spec.ts region='ShakableInjectionToken'}

@publicApi
export class InjectionToken<T> {
 /** @internal */
 readonly ngMetadataName = 'InjectionToken';
 readonly prov: never|undefined;
 constructor(protected _desc: string, options?: {
 providedIn?: Type<any>|'root'|'platform'|any|null, factory: () => T
 }) {
 this.prov = undefined;
 if (typeof options == 'number') {
 (typeof ngDevMode === 'undefined' || ngDevMode) &&
 assertLessThan(options, 0, 'Only negative numbers are supported here');
 // This is a special hack to assign __NG_ELEMENT_ID__ to this instance.
 // See `InjectorMarkers` (this as any).__NG_ELEMENT_ID__ = options;
 } else if (options !== undefined) {
 this.prov = defineInjectable({
 token: this,
 providedIn: options.providedIn || 'root',
 factory: options.factory,
 });
 }
 }
 toString(): string {
 return `InjectionToken ${this._desc}`;
 }
}

export interface InjectableDefToken<T> extends InjectionToken<T> {
 prov: never;
}

"/**
 * @license
 * Copyright Google LLC All Rights Reserved.
 * Use of this source code is governed by an MIT-style license that can be
 * found in the LICENSE file at
 * https://angular.io/license
 */
import {InjectionToken} from './di/injection_token';
import {Type} from './interface/type';
import {makePropDecorator} from './util/decorators';

A DI token that you can use to create a virtual [provider](guide/glossary#provider) that will populate the `entryComponents` field of components and NgModules based on its `useValue` property value. All components that are referenced in the `useValue` value (either directly or in a nested array or map) are added to the `entryComponents` property.

@usageNotes
The following example shows how the router can populate the `entryComponents` field of an NgModule based on a router configuration that refers to components.

typescript
// helper function inside the router
function provideRoutes(routes) {
 return [
 {provide: ROUTES, useValue: routes},
 {provide: ANALYZE_FOR_ENTRY_COMPONENTS, useValue: routes, multi: true}
];
}

// user code
let routes = [
 {path: '/root', component: RootComp},
 {path: '/teams', component: TeamsComp}
];

@NgModule({
 providers: [provideRoutes(routes)]
})
class ModuleWithRoutes {
 /**
 * @publicApi
 * @deprecated Since 9.0.0. With Ivy, this property is no longer necessary.
 */
 export const ANALYZE_FOR_ENTRY_COMPONENTS = new InjectionToken<any>('AnalyzeForEntryComponents');
}

/**
 * Type of the `Attribute` decorator / constructor function.
 * @publicApi
 * export interface AttributeDecorator {
 /**
 * Specifies that a constant attribute value should be injected.
 * The directive can inject constant string literals of host element attributes.
 * @usageNotes
 * Suppose we have an <input> element and want to know its `type`.
 *
 * html
 * <input type="text">
 *
 * A decorator can inject string literal `text` as in the following example.
 *
 * @example core/ts/metadata/metadata.ts region='attributeMetadata'
 * @publicApi
 * (name: string): any;
 * new(name: string): Attribute;
 }

 /**
 * Type of the Attribute metadata.
 * @publicApi
 * export interface Attribute {
 /**
 * The name of the attribute to be injected into the constructor.
 * attribute?: string;
 }

 /**
 * Type of the Query metadata.
 * @publicApi
 * export interface Query {
 descendants: boolean;
 first: boolean;
 read: any;
 isViewQuery: boolean;
 selector: any;
 static?: boolean;
 }

 /**
 * Base class for query metadata.
 * @see `ContentChildren`.
 * @see `ContentChild`.
 * @see `ViewChildren`.
 * @see `ViewChild`.
 * @publicApi
 * export abstract class Query {}

 /**
 * Type of the ContentChildren decorator / constructor function.
 * @see `ContentChildren`.
 * @publicApi
 * export interface ContentChildrenDecorator {
 /**
 * Parameter decorator that configures a content query.
 * Use to get the `QueryList` of elements or directives from the content DOM.
 * Any time a child element is added, removed, or moved, the query list will

```

be updated, and the changes observable of the query list will emit a new value.

Content queries are set before the `ngAfterContentInit` callback is called.

Does not retrieve elements or directives that are in other components' templates, since a component's template is always a black box to its ancestors.

**Metadata Properties:**

- selector** - The directive type or the name used for querying.
- descendants** - True to include all descendants, otherwise include only direct children.
- read** - Used to read a different token from the queried elements.

**@usageNotes**

Here is a simple demonstration of how the `ContentChildren` decorator can be used.

**@example**

```
core/di/ts/contentChildren/content_children_howto.ts region='HowTo'
```

**### Tab-pane example**

Here is a slightly more realistic example that shows how `ContentChildren` decorators can be used to implement a tab pane component.

**@example**

```
core/di/ts/contentChildren/content_children_example.ts region='Component'
```

**@Annotation**

```
(selector: Type<any>|InjectionToken<unknown>|Function|string, opts?: { descendants?: boolean, read?: any }): any;
new(selector: Type<any>|InjectionToken<unknown>|Function|string, opts?: { descendants?: boolean, read?: any }): Query;
```

Type of the `ContentChildren` metadata.

**@Annotation**

**@publicApi**

```
export type ContentChildren = Query;
export ContentChildrenDecorator = makePropDecorator(
 'ContentChildren',
 (selector?: any, data: any = {}) => ({ selector, first: false, isViewQuery: false, descendants: false, ...data }),
 Query);
```

Type of the `ContentChild` decorator / constructor function.

**@publicApi**

```
export interface ContentChildDecorator {
 // Parameter decorator that configures a content query.
 // Use to get the first element or the directive matching the selector from the content DOM.
 // If the content DOM changes, and a new child matches the selector, the property will be updated.
 // Content queries are set before the `ngAfterContentInit` callback is called.
 // Does not retrieve elements or directives that are in other components' templates, since a component's template is always a black box to its ancestors.
 // Metadata Properties:
 // selector - The directive type or the name used for querying.
 // read - Used to read a different token from the queried element.
 // static - True to resolve query results before change detection runs, false to resolve after change detection. Defaults to false.
 // @usageNotes
 // @example
 core/di/ts/contentChild/content_child_howto.ts region='HowTo'
```

**### Example**

**@example**

```
core/di/ts/contentChild/content_child_example.ts region='Component'
```

**@Annotation**

```
(selector: Type<any>|InjectionToken<unknown>|Function|string, opts?: { read?: any, static?: boolean }): any;
new(selector: Type<any>|InjectionToken<unknown>|Function|string, opts?: { read?: any, static?: boolean }): ContentChild;
```

Type of the `ContentChild` metadata.

**@publicApi**

```
export type ContentChild = Query;
export ContentChildDecorator = makePropDecorator(
 'ContentChild',
 (selector?: any, data: any = {}) => ({ selector, first: true, isViewQuery: false, descendants: true, ...data }),
 Query);
```

Type of the `ViewChildren` decorator / constructor function.

**@see** `ViewChildren`.

**@publicApi**

```
export interface ViewChildrenDecorator {
 // Parameter decorator that configures a view query.
 // Use to get the `QueryList` of elements or directives from the view DOM.
 // Any time a child element is added, removed, or moved, the query list will be updated, and the changes observable of the query list will emit a new value.
 // View queries are set before the `ngAfterViewInit` callback is called.
 // Metadata Properties:
 // selector - The directive type or the name used for querying.
 // read - Used to read a different token from the queried elements.
 // @usageNotes
 // @example
 core/di/ts/viewChildren/view_children_howto.ts region='HowTo'
```

**### Another example**

**@example**

```
core/di/ts/viewChildren/view_children_example.ts region='Component'
```

**@Annotation**

```
(selector: Type<any>|InjectionToken<unknown>|Function|string, opts?: { read?: any }): any;
new(selector: Type<any>|InjectionToken<unknown>|Function|string, opts?: { read?: any }): ViewChildren;
```

Type of the `ViewChildren` metadata.

**@publicApi**

```
export type ViewChildren = Query;
export ViewChildrenDecorator =
```

```

}
Inverts an inputs or outputs lookup such that the keys, which
were the minified keys, are part of the values, and the values are parsed so that
the publicName of the
property is the new key
e.g. for
class Comp {
 @Input() propName1: string;
 @Input('publicName2') declaredPropName2: number;
}
will be serialized as
{
 propName1: 'propName1',
 declaredPropName2: ['publicName2', 'declaredPropName2'],
}
which is then translated by the minifier as
{
 minifiedPropName1: 'propName1',
 minifiedPropName2: ['publicName2', 'declaredPropName2'],
}
becomes: (public name =>
minifiedName)
{
 'propName1': 'minifiedPropName1',
 'publicName2':
'minifiedPropName2',
}
Optionally the function can take `secondary` which will result in: (public
name => declared name)
{
 'propName1': 'propName1',
 'publicName2':
'declaredPropName2',
}
function invertObject<T>(obj?: {[P in keyof T]?: string|[string,
string]}, secondary?: {[key: string]: string}): {[P in keyof T]: string} {
 if (obj == null) return EMPTY_OBJ as any;
 const newLookup: any = {};
 for (const minifiedKey in obj) {
 if (obj.hasOwnProperty(minifiedKey)) {
 let publicName: string|[string, string] = obj[minifiedKey]!;
 let declaredName = publicName;
 if (Array.isArray(publicName)) {
 declaredName = publicName[1];
 publicName = publicName[0];
 }
 newLookup[publicName] = minifiedKey;
 if (secondary) {
 secondary[publicName] =
 declaredName as string;
 }
 }
 }
 return newLookup;
}
Create a directive definition object.
Example
class MyDirective {
 // Generated by Angular Template Compiler
 // [Symbol]
 syntax will not be supported by TypeScript until v2.7
 static dir = defineDirective({
 ...
 });
}
@codeGenApi
export const defineDirective =
 defineComponent as any
as<T>(directiveDefinition: {
 /** Directive type, needed to configure the injector. type:
 Type<T>;
 /** The selectors that will be used to match nodes to this directive. selectors?:
 CssSelectorList;
 /** A map of input names.
 /** The format is in: {[actualPropertyName:
 string]:(string|[string, string])}.
 /** Given:
 class MyComponent {
 @Input()
 publicInput1: string;
 @Input('publicInput2') declaredInput2: string;
 }
 is described as:
 {
 publicInput1: 'publicInput1',
 declaredInput2:
['declaredInput2', 'publicInput2'],
 }
 Which the minifier may translate to:
 {
 minifiedPublicInput1: 'publicInput1',
 minifiedDeclaredInput2: ['publicInput2',
'declaredInput2'],
 }
 This allows the render to re-construct the minified, public, and
declared names
of properties.
NOTE:
- Because declared and public name are usually
same we only generate the array
['declared', 'public'] format when they differ.
- The reason why
this API and `outputs` API is not the same is that `NgOnChanges` has
inconsistent behavior in that it uses
declared names rather than minified or public. For
this reason `NgOnChanges` will be deprecated and
removed in future version and this
API will be simplified to be consistent with `output`.
inputs?: {[P in keyof T]?: string | [string, string]};
/** A map of output names.
/** The
format is in: {[actualPropertyName: string]:string}.
/** Which the minifier may translate to:
{[minifiedPropertyName: string]:string}.
This allows the render to re-construct the minified and
non-minified names
of properties.
outputs?: {[P in keyof T]?: string};
/** A list
of optional features to apply.
/** See: { @link NgOnChangesFeature }, { @link ProvidersFeature },
{ @link InheritDefinitionFeature }
/** features?: DirectiveDefFeature[];
/** Function
executed by the parent template to allow child directive to apply host bindings.
hostBindings?:
HostBindingsFunction<T>;
/** The number of bindings in this directive `hostBindings` (including
pure fn bindings).
/** Used to calculate the length of the component's LView array, so we
can
pre-fill the array and set the host binding start index.
hostVars?: number;
/** Assign

```

was declared.

The template for a dynamically created view may be declared in a different view than it is inserted. We already track the "insertion view" (view where the template was inserted) in `LView[PARENT]`, but we also need access to the "declaration view" (view where the template was declared). Otherwise, we wouldn't be able to call the view's template function with the proper contexts. Context should be inherited from the declaration view tree, not the insertion view tree.

Example (AppComponent template):

```
<ng-template #foo></ng-template> <-- declared here -->
<some-comp [tpl]="foo"></some-comp> <-- inserted inside this component -->
```

The `<ng-template>` above is declared in the AppComponent template, but it will be passed into `SomeComp` and inserted there. In this case, the declaration view would be the AppComponent, but the insertion view would be `SomeComp`. When we are removing views, we would want to traverse through the insertion view to clean up listeners. When we are calling the template function during change detection, we need the declaration view to get inherited context.

`DECLARATION_VIEW`: `LView` or `null`; Points to the declaration component view, used to track transplanted `LView`'s. See: `DECLARATION_VIEW` which points to the actual `LView` where it was declared, whereas `DECLARATION_COMPONENT_VIEW` points to the component which may not be same as `DECLARATION_VIEW`.

Example:

```
<#VIEW #myComp>
<div *ngIf="true">
 <ng-template #myTpl>...</ng-template>
</div>
</#VIEW>
```

In the above case `DECLARATION_VIEW` for `myTpl` points to the `LView` of `ngIf` whereas `DECLARATION_COMPONENT_VIEW` points to `LView` of the `myComp` which owns the template.

The reason for this is that all embedded views are always check-always whereas the component view can be check-always or on-push. When we have a transplanted view it is important to determine if we have transplanted a view from check-always declaration to on-push insertion point. In such a case the transplanted view needs to be added to the `LContainer` in the declared `LView` and CD during the declared view CD (in addition to the CD at the insertion point.) (Any transplanted views which are intra Component are of no interest because the CD strategy of declaration and insertion will always be the same, because it is the same component.)

Queries already track moved views in `LView[DECLARATION_LCONTAINER]` and `LContainer[MOVED_VIEWS]`. However the queries also track `LView`'s which moved within the same component `LView`. Transplanted views are a subset of moved views, and we use `DECLARATION_COMPONENT_VIEW` to differentiate them. As in this example.

Example showing intra component `LView` movement.

```
<#VIEW #myComp>
<div *ngIf="condition; then thenBlock else elseBlock"></div>
<ng-template #thenBlock>Content to render when condition is true.</ng-template>
<ng-template #elseBlock>Content to render when condition is false.</ng-template>
</#VIEW>
```

The `thenBlock` and `elseBlock` is moved but not transplanted.

Example showing inter component `LView` movement (transplanted view).

```
<#VIEW #myComp>
<ng-template #myTpl>...</ng-template>
<insertion-component [template]="myTpl"></insertion-component>
```

In the above example `myTpl` is passed into a different component. If `insertion-component` instantiates `myTpl` and `insertion-component` is on-push then the `LContainer` needs to be marked as containing transplanted views and those views need to be CD as part of the declaration CD.

When change detection runs, it iterates over `[MOVED_VIEWS]` and CDs any child `LView`'s where the `DECLARATION_COMPONENT_VIEW` of the current component and the child `LView` does not match (it has been transplanted across components).

Note:

- `DECLARATION_COMPONENT_VIEW` points to itself if the `LView` is a component view (the simplest / most common case). see also: <https://hackmd.io/@mhevery/rJUjsvv9H> write up of the problem
- `LContainer[HAS_TRANSPLANTED_VIEWS]` which marks which `LContainer` has transplanted views.
- `LContainer[TRANSPLANT_HEAD]` and `LContainer[TRANSPLANT_TAIL]` storage for transplanted `LView[DECLARATION_LCONTAINER]` similar problem for queries
- `LContainer[MOVED_VIEWS]` similar problem for queries
- `DECLARATION_COMPONENT_VIEW`: `LView`; A declaration point of embedded views (ones instantiated based on the content of a `<ng-template>`), null for other types of views. We need to track all embedded views created from a given

```

declaration point so we can prepare
 * query matches in a proper order (query matches are ordered based on their
declaration point and
 * _not_ the insertion point).\n

 * Stores a set of OpCodes to process
`HostBindingsFunction` associated with a current view.\n
 * In order to invoke `HostBindingsFunction` we
need:\n
 * 1. `elementIdx`: Index to the element associated with the `HostBindingsFunction`.\n
 * 2. `directiveIdx`:
Index to the directive associated with the `HostBindingsFunction`. (This will\n
 * become the context for the
`HostBindingsFunction` invocation.)\n
 * 3. `bindingRootIdx`: Location where the bindings for the
`HostBindingsFunction` start. Internally\n
 * `HostBindingsFunction` binding indexes start from `0` so we need to
add `bindingRootIdx` to\n
 * it.\n
 * 4. `HostBindingsFunction`: A host binding function to execute.\n
 * The
above information needs to be encoded into the `HostBindingOpCodes` in an efficient manner.\n
 * 1.
`elementIdx` is encoded into the `HostBindingOpCodes` as `~elementIdx` (so a negative number);\n
 * 2.

```

```

`directiveIdx`\n * 3. `bindingRootIdx`\n * 4. `HostBindingsFunction` is passed in as is.\n * The
`HostBindingOpCodes` array contains:\n * - negative number to select the element index.\n * - followed by 1 or
more of:\n * - a number to select the directive index\n * - a number to select the bindingRoot index\n * - and a
function to invoke.\n * ## Example\n * ```\n * const hostBindingOpCodes = [\n * ~30, //
Select element 30\n * 40, 45, MyDir.dir.hostBindings // Invoke host bindings on MyDir on element 30;\n *
// directiveIdx = 40; bindingRootIdx = 45;\n * 50, 55, OtherDir.dir.hostBindings // Invoke host
bindings on OtherDir on element 30\n * // directiveIdx = 50; bindingRootIdx = 55;\n *]\n *
```\n * ## Pseudocode\n * ```\n * const hostBindingOpCodes = tView.hostBindingOpCodes;\n * if
(hostBindingOpCodes === null) return;\n * for (let i = 0; i < hostBindingOpCodes.length; i++) {\n * const opCode
= hostBindingOpCodes[i] as number;\n * if (opCode < 0) {\n * // Negative numbers are element indexes.\n *
setSelectedIndex(~opCode);\n * } else {\n * // Positive numbers are NumberTuple which store
bindingRootIndex and directiveIndex.\n * const directiveIdx = opCode;\n * const bindingRootIdx =
hostBindingOpCodes[++i] as number;\n * const hostBindingFn = hostBindingOpCodes[++i] as
HostBindingsFunction<any>;\n * setBindingRootForHostBindings(bindingRootIdx, directiveIdx);\n * const
context = IView[directiveIdx];\n * hostBindingFn(RenderFlags.Update, context);\n * }}\n * ```\n *
`^`\n * export interface HostBindingOpCodes extends Array<number|HostBindingsFunction<any>> {\n * __brand__:

this\n * flag can remain turned un until there is first successful (no exception) pass. This means that\n * individual
styling instructions keep track of if they have already been added to the linked\n * list to prevent double adding.\n *
firstUpdatePass: boolean;\n * // Static data equivalent of LView.data[]. Contains TNodes, PipeDefInternal or
TI18n.\n * data: TData;\n * // The binding start index is the index at which the data array\n * starts to store
bindings only. Saving this value ensures that we\n * will begin reading bindings at the correct point in the array
when\n * we are in update mode.\n * -1 means that it has not been initialized.\n * bindingStartIndex:
number;\n * // The index where the `\"expando\"` section of `LView` begins. The expando\n * section

```

contains injectors, directive instances, and host binding values.

- Unlike the "decls" and "vars" sections of `LView``, the length of this section cannot be calculated at compile-time because directives are matched at runtime to preserve locality.
- We store this start index so we know where to start checking host bindings in `setHostBindings``.
- `expandoStartIndex: number;` Whether or not there are any static view queries tracked on this view.
- We store this so we know whether or not we should do a view query refresh after creation mode to collect static query results.
- `staticViewQueries: boolean;` Whether or not there are any static content queries tracked on this view.
- We store this so we know whether or not we should do a content query refresh after creation mode to collect static query results.
- `staticContentQueries: boolean;` A reference to the first child node located in the view.
- `firstChild: TNode|null;` Stores the OpCodes to be replayed during change-detection to process the `HostBindings``.
- See `HostBindingOpCodes`` for encoding details.
- `hostBindingOpCodes: HostBindingOpCodes|null;` Full registry of directives and components that may be found in this view.
- It's necessary to keep a copy of the full def list on the `TView`` so it's possible to render template functions without a host component.
- `directiveRegistry: DirectiveDefList|null;` Full registry of pipes that may be found in this view.
- The property is either an array of `PipeDefs`s`` or a function which returns the array of `PipeDefs`s``. The function is necessary to be able to support forward declarations.
- It's necessary to keep a copy of the full def list on the `TView`` so it's possible to render template functions without a host component.
- `pipeRegistry: PipeDefList|null;` Array of `ngOnInit, ngOnChanges` and `ngDoCheck` hooks that should be executed for this view in creation mode.
- This array has a flat structure and contains `TNode` indices, directive indices (where an instance can be found in `LView``) and hook functions. `TNode` index is followed by the directive index and a hook function. If there are multiple hooks for a given `TNode`, the `TNode` index is not repeated and the next lifecycle hook information is stored right after the previous hook function. This is done so that at runtime the system can efficiently iterate over all of the functions to invoke without having to make any decisions/lookups.
- `preOrderHooks: HookData|null;` Array of `ngOnChanges` and `ngDoCheck` hooks that should be executed for this view in update mode.
- This array has the same structure as the `preOrderHooks`` one.
- `preOrderCheckHooks: HookData|null;` Array of `ngAfterContentInit` and `ngAfterContentChecked` hooks that should be executed for this view in creation mode.
- Even indices: Directive index
- Odd indices: Hook function
- `contentHooks: HookData|null;` Array of `ngAfterContentChecked` hooks that should be executed for this view in update mode.
- Even indices: Directive index
- Odd indices: Hook function
- `contentCheckHooks: HookData|null;` Array of `ngAfterViewInit` and `ngAfterViewChecked` hooks that should be executed for this view in creation mode.
- Even indices: Directive index
- Odd indices: Hook function
- `viewHooks: HookData|null;` Array of `ngAfterViewChecked` hooks that should be executed for this view in update mode.
- Even indices: Directive index
- Odd indices: Hook function
- `viewCheckHooks: HookData|null;` Array of `ngOnDestroy` hooks that should be executed when this view is destroyed.
- Even indices: Directive index
- Odd indices: Hook function
- `destroyHooks: DestroyHookData|null;` When a view is destroyed, listeners need to be released and outputs need to be unsubscribed. This cleanup array stores both listener data (in chunks of 4) and output data (in chunks of 2) for a particular view. Combining the arrays saves on memory (70 bytes per array) and on a few bytes of code size (for two separate for loops).
- If it's a native DOM listener or output subscription being stored:
 - 1st index is: event name `name = tView.cleanup[i+0]`
 - 2nd index is: index of native element or a function that retrieves global target (window, document or body) reference based on the native element:
 - `typeof idxOrTargetGetter === 'function'`: global target getter function
 - `typeof idxOrTargetGetter === 'number'`: index of native element
 - 3rd index is: index of listener function `listener = LView[CLEANUP][tView.cleanup[i+2]]`
 - 4th index is: `useCaptureOrIndx = tView.cleanup[i+3]`
 - `typeof useCaptureOrIndx === 'boolean'`: useCapture boolean
 - `typeof useCaptureOrIndx === 'number'`:
 - `useCaptureOrIndx >= 0` `removeListener = LView[CLEANUP][useCaptureOrIndx]`
 - `useCaptureOrIndx < 0` `subscription = LView[CLEANUP][-useCaptureOrIndx]`
- If it's an output subscription or query list

destroy hook:\n * 1st index is: output unsubscribe function / query list destroy function\n * 2nd index is: index of function context in LView.cleanupInstances[]\n *

```

created and track query results.

- `isParent``: This is used in conjunction with `currentTNode``. If `isParent`` is `true``: then `currentTNode`` points to a parent node. If `false``: then `currentTNode`` points to previous node (sibling).
- `isParent: boolean``: Index of currently selected element in `LView``. Used by binding instructions. Updated as part of advance instruction.
- `selectedIndex: number``: Current pointer to the binding index.
- `bindingIndex: number``: The last `viewData` retrieved by `nextContext().`` Allows building `nextContext().`` and `reference().`` calls.
 - e.g. `const inner = x().$implicit; const outer = x().$implicit;``
 - `contextLView: LView``: Store the element depth count. This is used to identify the root elements of the template so that we can then attach patch data `LView`` to only those elements. We know that those are the only places where the patch data could change, this way we will save on number of places where the patching occurs.
 - `elementDepthCount: number``: Current namespace to be used when creating elements.
 - `currentNamespace: string|null``: The root index from which pure function instructions should calculate their binding indices. In component views, this is `TView.bindingStartIndex``. In a host binding context, this is the `TView.expandoStartIndex + any dirs/hostVars before the given dir.``
 - `bindingRootIndex: number``: Current index of a `View` or `Content Query` which needs to be processed next. We iterate over the list of `Queries` and increment current query index at every step.
 - `currentQueryIndex: number``: When host binding is executing this points to the directive index. `TView.data[currentDirectiveIndex]`` is `DirectiveDef``. `LView[currentDirectiveIndex]`` is directive instance.
 - `currentDirectiveIndex: number``: Are we currently in `i18n`` block as denoted by `elementStart`` and `elementEnd``. This information is needed because while we are in `i18n`` block all elements must be pre-declared in the translation. (i.e. `'Hello #2World/#2!`` pre-declares element at `#2`` location.) This allocates `TNodeType.Placeholder`` element at location `#2``. If translator removes `#2`` from translation than the runtime must also ensure the element at `#2`` does not get inserted into the DOM. The translation does not carry information about deleted elements. Therefore the only way to know that an element is deleted is that it was not pre-declared in the translation. This flag works by ensuring that elements which are created without pre-declaration (`TNodeType.Placeholder``) are not inserted into the DOM render tree. (It does mean that the element still gets instantiated along with all of its behavior [directives])
 - `inI18n: boolean``: All implicit instruction state is stored here. It is useful to have a single object where all of the state is stored as a mental model (rather it being spread across many different variables).
 - PERF NOTE:** Turns out that writing to a true global variable is slower than having an intermediate object with properties.
- `interface InstructionState {``
 - `current`LFrame``: `null`` if we have not called `enterView.``
 - `LFrame: LFrame``: Stores whether directives should be matched to elements.
 - When template contains `ngNonBindable`` then we need to prevent the runtime from matching directives on children of that element. Example:

```
<my-comp my-directive>
ngNonBindable>
<my-comp my-directive>
</my-comp>
<div
ngNonBindable>
</my-comp>
</div>
```

 - Should match component / directive.
 - Should not match component / directive because we are in `ngNonBindable.``
 - `bindingsEnabled: boolean``: In this mode, any changes in bindings will throw an `ExpressionChangedAfterChecked`` error. Necessary to support `ChangeDetectorRef.checkNoChanges().`` `checkNoChanges`` Runs only in `devmode=true`` and verifies that no unintended changes exist in the change detector or its children.
 - `isInCheckNoChangesMode: boolean``
- `const instructionState: InstructionState = {``
 - `LFrame``: `createLFrame(null,``
 - `bindingsEnabled: true,``
 - `isInCheckNoChangesMode: false,``
 - Returns true if the instruction state stack is empty. Intended to be called from tests only (tree shaken otherwise).
 - `next`` function `specOnlyIsInstructionStateEmpty(): boolean {`` return `instructionState.LFrame.parent === null;``
 - `next`` function `getElementDepthCount() {`` return `instructionState.LFrame.elementDepthCount;``
 - `next`` function `increaseElementDepthCount() {`` return `instructionState.LFrame.elementDepthCount++;``
 - `next`` function `decreaseElementDepthCount() {`` return `instructionState.LFrame.elementDepthCount--;``
 - `next`` function `getBindingsEnabled(): boolean {`` return `instructionState.bindingsEnabled;``
 - Enables directive matching on elements. Example:

```

```\n * <my-comp my-directive>\n * Should match component / directive.\n * </my-comp>\n * <div
ngNonBindable>\n * <!-- disableBindings() -->\n * <my-comp my-directive>\n * Should not match component
/ directive because we are in ngNonBindable.\n * </my-comp>\n * <!-- enableBindings() -->\n * </div>\n * ```\n

* A module to facilitate use of a Trusted Types policy internally within\n * Angular. It lazily constructs the Trusted
Types policy, providing helper\n * utilities for promoting strings to Trusted Types. When Trusted Types are not\n *
available, strings are used as a fallback.\n * @security All use of this module is security-sensitive and should go
through\n * security review.\n */\nimport {global} from './global';\nimport {TrustedHTML, TrustedScript,
TrustedScriptURL, TrustedTypePolicy, TrustedTypePolicyFactory} from './trusted_type_defs';\n\n * The
Trusted Types policy, or null if Trusted Types are not\n * enabled/supported, or undefined if the policy has not been
created yet.\n */\nlet policy: TrustedTypePolicy|null|undefined;\n\n * Returns the Trusted Types policy, or null
if Trusted Types are not\n * enabled/supported. The first call to this function will create the policy.\n */\nfunction
getPolicy(): TrustedTypePolicy|null {\n if (policy === undefined) {\n policy = null;\n if (global.trustedTypes)
{\n try {\n policy = (global.trustedTypes as TrustedTypePolicyFactory).createPolicy('angular', {\n
createHTML: (s: string) => s,\n createScript: (s: string) => s,\n createScriptURL: (s: string) => s,\n
});\n } catch {\n // trustedTypes.createPolicy throws if called with a name that is\n // already registered,
even in report-only mode. Until the API changes,\n // catch the error not to break the applications functionally.
In such\n // cases, the code will fall back to using strings.\n }\n }\n }\n return policy;\n}\n\n/**\n *
Unsafely promote a string to a TrustedHTML, falling back to strings when\n * Trusted Types are not available.\n *
@security This is a security-sensitive function; any use of this function\n * must go through security review. In
particular, it must be assured that the\n * provided string will never cause an XSS vulnerability if used in a context\n
* that will be interpreted as HTML by a browser, e.g. when assigning to\n * element.innerHTML.\n */\nexport
function trustedHTMLFromString(html: string): TrustedHTML|string {\n return getPolicy()?.createHTML(html) ||
html;\n}\n\n/**\n * Unsafely promote a string to a TrustedScript, falling back to strings when\n * Trusted Types are
not available.\n * @security In particular, it must be assured that the provided string will\n * never cause an XSS
vulnerability if used in a context that will be\n * interpreted and executed as a script by a browser, e.g. when calling
eval.\n */\nexport function trustedScriptFromString(script: string): TrustedScript|string {\n return
getPolicy()?.createScript(script) || script;\n}\n\n/**\n * Unsafely promote a string to a TrustedScriptURL, falling
back to strings\n * when Trusted Types are not available.\n * @security This is a security-sensitive function; any use
of this function\n * must go through security review. In particular, it must be assured that the\n * provided string

```

will never cause an XSS vulnerability if used in a context that will cause a browser to load and execute a resource, e.g. when assigning to `script.src`.

`export function trustedScriptURLFromString(url: string): TrustedScriptURL {`  
`return getPolicy()?.createScriptURL(url) || url;`  
`}`

Unsafely call the Function constructor with the given string arguments. It is only available in development mode, and should be stripped out of production code.

`@security` This is a security-sensitive function; any use of this function must go through security review. In particular, it must be assured that it is only called from development code, as use in production code can lead to XSS vulnerabilities.

`export function newTrustedFunctionForDev(...args: string[]): Function {`  
`if (typeof ngDevMode === 'undefined') {`  
`throw new Error('newTrustedFunctionForDev should never be called in production');`  
`}`  
`if (!global.trustedTypes) {`  
`// In environments that don't support Trusted Types, fall back to the most`  
`// straightforward implementation:`  
`return new Function(...args);`  
`}`  
`// Chrome currently does not support passing TrustedScript to the Function`  
`// constructor. The following implements the workaround proposed on the page`  
`// below, where the Chromium bug is also referenced:`  
`// https://github.com/w3c/webappsec-trusted-types/wiki/Trusted-Types-for-function-`  
`// constructor`  
`const fnArgs = args.slice(0, -1).join(',');`  
`const fnBody = args.pop()!.toString();`  
`const body =`  
``function anonymous(${fnArgs}) { ${fnBody} }`;`  
`// Using eval directly confuses the compiler and`  
`// prevents this module from`  
`// being stripped out of JS binaries even if not used. The global['eval']`  
`// indirection`  
`// fixes that.`  
`const fn = global['eval'](trustedScriptFromString(body) as string) as Function;`  
`// To completely`  
`// mimic the behavior of calling "new Function", two more`  
`// things need to happen:`  
`// 1. Stringifying the`  
`// resulting function should return its source code`  
`fn.toString = () => body;`  
`// 2. When calling the resulting`  
`// function, `this` should refer to `global``  
`return fn.bind(global);`  
`}`

When Trusted Types support in Function constructors is widely available, the implementation of this function can be simplified to:

`export function newTrustedFunctionForDev(...args: string[]): Function {`  
`return new Function(...args.map(a => trustedScriptFromString(a)));`  
`}`

/**
 * A pattern that recognizes a commonly useful
 * subset of URLs that are safe.
 * This regular expression matches a subset of URLs that will not cause script
 * execution if used in URL context within a HTML document. Specifically, this
 * regular expression matches if
 * (comment from here on and regex copied from Soy's EscapingConventions):
 * (1) Either an allowed protocol (http, https, mailto or ftp).
 * (2) or no protocol. A protocol must be followed by a colon. The below
 * allows that by allowing colons only after one of the characters [/?#].
 * A colon after a hash (#) must be in the
 * fragment.
 * Otherwise, a colon after a (?) must be in a query.
 * Otherwise, a colon after a single solidus (/)
 * must be in a path.
 * Otherwise, a colon after a double solidus (//) must be in the authority
 * (before port).
 * The pattern disallows &, used in HTML entity declarations before
 * one of the characters in [/?#]. This
 * disallows HTML entities used in the
 * protocol name, which should never happen, e.g. "ttp" for
 * "http".
 * It also disallows HTML entities in the first path part of a relative path,
 * e.g. "foo<bar/baz". Our
 * existing escaping functions should not produce
 * that. More importantly, it disallows masking of a colon,
 * e.g.
 * "javascript::...".
 * This regular expression was taken from the Closure sanitization library.

[7]: number;\n *\n * // Necessary to find directive indices for a particular node.\n * [TNode]:
TElementNode|TElementContainerNode|TContainerNode;\n * }\n */\n\n**\n * Factory for creating instances of
injectors in the NodeInjector.\n * This factory is complicated by the fact that it can resolve `multi` factories as
well.\n * NOTE: Some of the fields are optional which means that this class has two hidden classes.\n * - One
without `multi` support (most common)\n * - One with `multi` values, (rare).\n * Since VMs can cache up to 4

```

inline hidden classes this is OK.

* - Single factory: Only `resolving` and `factory` is defined.

* - `providers` factory: `componentProviders` is a number and `index = -1`.

* - `viewProviders` factory: `componentProviders` is a number and `index` points to `providers`.

```

export class NodeInjectorFactory {
  /**
   * The inject implementation to be activated when using the factory.
   *
   * @param injectImpl: null | (<T>(token: Type<T>|InjectionToken<T>, flags?: InjectFlags) => T);
   *
   * Marker set to true during factory invocation to see if we get into recursive loop.
   *
   * Recursive loop causes an error to be displayed.
   *
   * resolving = false;
   *
   * Marks that the token can see other Tokens declared in `viewProviders` on the same node.
   *
   * canSeeViewProviders: boolean;
   *
   * An array of factories to use in case of `multi` provider.
   *
   * multi?: Array<() => any>;
   *
   * Number of `multi`-providers which belong to the component.
   *
   * This is needed because when multiple components and directives declare the `multi` provider they have to be concatenated in the correct order.
   *
   * Example:
   *
   * If we have a component and directive active on a single element as declared here
   *
   * component:
   *   provides: [ { provide: String, useValue: 'component', multi: true } ],
   *   viewProvides: [ { provide: String, useValue: 'componentView', multi: true } ],
   *   directive:
   *     provides: [ { provide: String, useValue: 'directive', multi: true } ],
   *
   * Then the expected results are:
   *
   * providers: ['component', 'directive']
   * viewProviders: ['component', 'componentView', 'directive']
   *
   * The way to think about it is that the `viewProviders` have been inserted after the component but before the directives, which is why we need to know how many `multi`s have been declared by the component.
   *
   * componentProviders?: number;
   *
   * Current index of the Factory in the `data`. Needed for `viewProviders` and `providers` merging.
   *
   * See `providerFactory`.
   *
   * index?: number;
   *
   * Because the same `multi` provider can be declared in `provides` and `viewProvides` it is possible for `viewProvides` to shadow the `provides`. For this reason we store the `provideFactory` of the `providers` so that `providers` can be extended with `viewProviders`.
   *
   * Example:
   *
   * Given:
   *
   * provides: [ { provide: String, useValue: 'all', multi: true } ],
   * viewProvides: [ { provide: String, useValue: 'viewOnly', multi: true } ],
   *
   * We have to return `['all']` in case of content injection, but `['all', 'viewOnly']` in case of view injection. We further have to make sure that the shared instances (in our case `all`) are the exact same instance in both the content as well as the view injection. (We have to make sure that we don't double instantiate.) For this reason the `viewProvides` `Factory` has a pointer to the shadowed `provides` factory so that it can instantiate the `providers` (['all']) and then extend it with `viewProviders` (['all'] + ['viewOnly'] = ['all', 'viewOnly']).
   *
   * providerFactory?: NodeInjectorFactory | null;
   *
   * constructor(
   *   /**
   *    * Factory to invoke in order to create a new instance.
   *    *
   *    * @param public factory: (this: NodeInjectorFactory, _: undefined,
   *    *   /**
   *    *    * array where injectables tokens are stored. This is used in
   *    *    * case of an error reporting to produce friendlier errors.
   *    *    *
   *    * @param tData: TData,
   *    *   /**
   *    *    * array where existing instances of injectables are stored. This is used in case
   *    *    * of multi shadow is needed. See `multi` field documentation.
   *    *    *
   *    * @param IView: LView,
   *    *   /**
   *    *    * The TNode of the same element injector.
   *    *    *
   *    * @param tNode: TDirectiveHostNode) => any,
   *    *   /**
   *    *    * Set to `true` if the token is declared in `viewProviders` (or if it is component).
   *    *    *
   *    * @param isViewProvider: boolean,
   *    *    * injectImplementation: null | (<T>(token: Type<T>|InjectionToken<T>, flags?: InjectFlags) => T)) {
   *    *      ngDevMode && assertDefined(factory, 'Factory not specified');
   *    *      ngDevMode && assertEqual(typeof factory, 'function', 'Expected factory function.');
```

this.canSeeViewProviders = isViewProvider; this.injectImpl = injectImplementation; }

export function isFactory(obj: any): obj is NodeInjectorFactory { return obj instanceof NodeInjectorFactory; }

// Note: This hack is necessary so we don't erroneously get a circular dependency // failure based on types.

```

export const unusedValueExportToPlacateAjd = 1;
import {KeyValueArray} from './util/array_utils';
import {TStylingRange} from './interfaces/styling';
import {TIcu} from './i18n';
import {CssSelector} from './projection';
import {RNode} from './renderer_dom';
import {LView, TView} from './view';
TNodeType corresponds to the {@link TNode} `type` property.
NOTE: type IDs are such that we use each bit to denote a type. This is done so that we can easily check if the `TNode` is of more

```

than one type.
`if (tNode.type === TNodeType.Text || tNode.type === TNodeType.Element)` can be written as:
`if (tNode.type & (TNodeType.Text | TNodeType.Element))`
However any given `TNode` can only be of one type.
`export const enum TNodeType {`
`Text = 0b1,` // The TNode contains information about a DOM element aka `{ @link RText}`.
`Element = 0b10,` // The TNode contains information about a DOM element aka `{ @link RElement}`.
`Container = 0b100,` // The TNode contains information about an `<ng-container>` element `{ @link RNode}`.
`ElementContainer = 0b1000,` // The TNode contains information about an `<ng-content>` projection.
`Projection = 0b10000,` // The TNode contains information about an ICU comment used in `i18n`.
`Icu = 0b100000,` // Special node type representing a placeholder for future `TNode` at this location.
`I18n = 0b1000000,` // I18n translation blocks are created before the element nodes which they contain. (I18n blocks can span over many elements.)
Because `i18n` `TNode`s (representing text) are created first they often may need to point to element `TNode`s which are not yet created. In such a case we create a `Placeholder` `TNode`. This allows the `i18n` to structurally link the `TNode`s together without knowing any information about the future nodes which will be at that location.
On `firstCreatePass` When element instruction executes it will try to create a `TNode` at that location. Seeing a `Placeholder` `TNode` already there tells the system that it should reuse existing `TNode` (rather than create a new one) and just update the missing information.
`Placeholder = 0b1000000,` // Combined Types These should never be used for `TNode.type` only as a useful way to check if `TNode.type` is one of several choices.
// See: <https://github.com/microsoft/TypeScript/issues/35875> why we can't refer to existing enum.
`AnyRNode = 0b11,` // Text | Element,
`AnyContainer = 0b1100,` // Container | ElementContainer,
// See:
`Converts TNodeType into human readable text.` Make sure this matches with
`TNodeType`
`export function toTNodeTypeAsString(tNode: TNodeType): string {`
`let text = "";`
`if (tNode & TNodeType.Text) text += "Text";`
`if (tNode & TNodeType.Element) text += "Element";`
`if (tNode & TNodeType.Container) text += "Container";`
`if (tNode & TNodeType.ElementContainer) text += "ElementContainer";`
`if (tNode & TNodeType.Projection) text += "Projection";`
`if (tNode & TNodeType.Icu) text += "Icu";`
`if (tNode & TNodeType.Placeholder) text += "Placeholder";`
`return text.length > 0 ? text.substring(1) : text;`
`}`
Corresponds to the `TNode.flags` property.
`export const enum TNodeFlags {`
`isDirectiveHost = 0x1,` // This bit is set if the node is a host for any directive (including a component).
`isComponentHost = 0x2,` // This bit is set if the node is a host for a component. Setting this bit implies that the `isDirectiveHost` bit is set as well.
`isProjected = 0x4,` // This bit is set if the node has been projected.
`hasContentQuery = 0x8,` // This bit is set if any directive on this node has content queries.
`hasClassInput = 0x10,` // This bit is set if the node has any `"class"` inputs.
`hasStyleInput = 0x20,` // This bit is set if the node has any `"style"` inputs.
`isDetached = 0x40,` // This bit is set if the node has been detached by `i18n`.
`hasHostBindings = 0x80,` // This bit is set if the node has directives with host bindings. This flag allows us to guard host-binding logic and invoke it only on nodes that actually have directives with host bindings.
Corresponds to the `TNode.providerIndexes` property.
`export const enum TNodeProviderIndexes {`
`ProvidersStartIndexMask = 0b00000000000000000000000000000000,` // The index of the first provider on this node is encoded on the least significant bits.
`CptViewProvidersCountShift = 20,` // The count of view providers from the component on this node is encoded on the 20 most significant bits.
`CptViewProvidersCountShifter = 0b00000000000000000000000000000000,` // A set of marker values to be used in the attributes arrays. These markers indicate that some items are not regular attributes and the processing should be adapted accordingly.
`AttributeMarker = 0,` // An implicit marker which indicates that the value in the array are of `attributeKey`, `attributeValue` format.
NOTE: This is implicit as it is the type when no marker is present in array. We indicate that it should not be present at runtime by the negative number.
`ImplicitAttributes = -1,` // Marker indicates that the following 3 values in the attributes array are: `namespaceUri`, `attributeName`, `attributeValue` in that order.

instruction can create `Hello`, `World` and `!` text nodes. It can also insert `Hello` and `!` text node as a child of `

`, but it can't insert `World` because the `` node has not yet been created. In such a case the `` `TNode` will have an array which will direct the `` to not only insert itself in front of `!` but also to insert the `World` (created by `!start`) into `` itself.

```

Pseudo code:
if (insertBeforeIndex === null) {
  // append as normal
} else if (Array.isArray(insertBeforeIndex)) {
  // First insert current `TNode` at correct location
  const currentNode = IView[this.index];
  parentNode.insertBefore(currentNode, IView[this.insertBeforeIndex[0]]);
  // Now append all of the children
  for(let i=1; i<this.insertBeforeIndex; i++) {
    currentNode.appendChild(IView[this.insertBeforeIndex[i]]);
  } else {
    parentNode.insertBefore(IView[this.index], IView[this.insertBeforeIndex]);
  }
}
- null: Append as normal using `parentNode.appendChild`
- number: Append using `parentNode.insertBefore(IView[this.index], IView[this.insertBeforeIndex])`

```

Because `!start` executes before nodes are created, on `TVIEW.firstCreatePass` it is not possible for `!start` to set the `insertBeforeIndex` value as the corresponding `TNode` has not yet been created. For this reason the `!start` creates a `TNodeType.Placeholder` `TNode` at that location. See `TNodeType.Placeholder` for more information.

`insertBeforeIndex`: InsertBeforeIndex; `injectorIndex`: number; The index of the closest injector in this node's LView. If the index === -1, there is no injector on this node or any ancestor node in this view. If the index !== -1, it is the index of this node's injector OR the index of a parent injector in the same view. We pass the parent injector index down the node tree of a view so it's possible to find the parent injector without walking a potentially deep node tree. Injector indices are not set across view boundaries because there could be multiple component hosts. If `tNode.injectorIndex` === `tNode.parent.injectorIndex`, then the index belongs to a parent injector. `injectorIndex`: number;

`directiveStart`: number; `directiveEnd`: number; NOTE: The first directive is always component (if present). `directiveStart`: number; `directiveEnd`: number; The area right behind the `directiveStart-directiveEnd` range is used to allocate the `HostBindingFunction` vars (or null if no bindings.) Therefore `directiveEnd` is used to set `LFrame.bindingRootIndex` before `HostBindingFunction` is executed. `directiveEnd`: number; `directiveStylingLast`: number; Stores the last directive which had a styling instruction. Initial value of this is -1 which means that no `hostBindings` styling instruction has executed. As `hostBindings` instructions execute they set the value to the index of the `DirectiveDef` which contained the last `hostBindings` styling instruction. Valid values are: -1 No `hostBindings` instruction has executed. `directiveStart <= directiveStylingLast < directiveEnd`: Points to the `DirectiveDef` of the last styling instruction which executed in the `hostBindings`. This data is needed so that styling instructions know which static styling data needs to be collected from the `DirectiveDef.hostAttrs`. A styling instruction needs to collect all data since last styling instruction. `directiveStylingLast`: number;

`propertyBindings`: number[]; Stores indexes of property bindings. This field is only set in the ngDevMode and holds indexes of property bindings so TestBed can get bound property metadata for a given node. `propertyBindings`: number[]; `isComponent`: boolean; `isProjected`: boolean; `hasContentQuery`: boolean; `hasClassInput`: boolean; `hasStyleInput`: boolean; etc. `flags`: TNodeFlags; This number stores two values using its bits: - the index of the first provider on that node (first 16 bits) - the count of view providers from the component on this node (last 16 bits) // TODO(misko): break this into actual vars. `providerIndexes`: TNodeProviderIndexes; The value name associated with this node. if type: `TNodeType.Text`: text value `TNodeType.Element`: tag name `TNodeType.ICUContainer`: `Ticu` value: any; Attributes associated with an element. We need to store attributes to support various use-cases (attribute injection, content projection with selectors, directives matching). Attributes are stored statically because reading them from the DOM would be way too slow for content projection and queries. Since attrs will always be calculated first, they will never need to be marked undefined by other instructions. For regular attributes a name of an attribute and its value alternate in the array. e.g. ['role', 'checkbox'] This array can contain flags that will indicate "special attributes" (attributes with

namespaces, attributes extracted from bindings and outputs).\n *^n attrs: TAttributes|null;\n\n /**\n * Same as `TNode.attrs` but contains merged data across all directive host bindings.\n *\n * We need to keep `attrs` as unmerged so that it can be used for attribute selectors.\n *\n * We merge attrs here so that it can be used in a performant way for initial rendering.\n *\n * The `attrs` are merged in first pass in following order:\n * - Component's `hostAttrs`\n * - Directives' `hostAttrs`\n * - Template `TNode.attrs` associated with the current `TNode`.\n */\n mergedAttrs: TAttributes|null;\n\n /**\n * A set of local names under which a given element is exported in a template and\n * visible to queries. An entry in this array can be created for different reasons:\n * - an element itself is referenced, ex.: `

`\n * - a component is referenced, ex.: ``\n * - a directive is referenced, ex.: `` => `["foo", -1]`\n * - `` => `["foo", myCmptIdx]`\n * - `

Open Source Used In NBAR SD-AVC 4.4.0 2835

projection setup. `projection` size is equal to the number of projections `<ng-content>`. The size of `c1` will be `1` because `<child>` has only one `<ng-content>`. We store `projection` with the host (`c1`, `c2`) rather than the `<ng-content>` (`cont1`) because the same component (`<child>`) can be used in multiple locations (`c1`, `c2`) and as a result have different set of nodes to project. Without `projection` it would be difficult to efficiently traverse nodes to be projected.

If `typeof projection === 'number'` then `TNode` is a `<ng-content>` element. `projection` is an index of the host's `projection` Nodes. This would return the first head node to project. `getHost(currentTNode).projection[currentTNode.projection]`. When projecting nodes the parent node retrieved may be a `<ng-content>` node, in which case the process is recursive in nature.

If `projection` is of type `RNode[][]` than we have a collection of native nodes passed as projectable nodes during dynamic component creation.

`projection`:

```
(TNode|RNode[])[number|null];
```

A collection of all `style` static values for an element (including from host). This field will be populated if and when:

- There are one or more initial `style`'s on an element (e.g. `<div style="width:200px;">`)
- There are one or more initial `style`'s on a directive/component host (e.g. `@Directive({host: {style: "width:200px;" } })`)

`styles`: `string|null`

A collection of all `style` static values for an element excluding host sources. Populated when there are one or more initial `style`'s on an element (e.g. `<div style="width:200px;">`). Must be stored separately from `tNode.styles` to facilitate setting directive inputs that shadow the `style` property. If we used `tNode.styles` as is for shadowed inputs, we would feed host styles back into directives as `"inputs"`. If we used `tNode.attrs`, we would have to concatenate the attributes on every template pass. Instead, we process once on first create pass and store here.

```
stylesWithoutHost: string|null;
```

A `KeyValueArray` version of residual `styles`.

When there are styling instructions than each instruction stores the static styling which is of lower priority than itself. This means that there may be a higher priority styling than the instruction.

Imagine:

```
<div style="color: highest;" my-dir>
@Directive({
  host: {
    style: 'color: lowest;',
    [styles.color]: 'exp' // styleProp('color', ctx.exp);
  })

```

In the above case: `color: lowest` is stored with `styleProp('color', ctx.exp)`; `color: highest` is the residual and is stored here.

`undefined`: not initialized. `null`: initialized but `styles` is `null`.

```
KeyValueArray<any>|undefined|null;
```

A `KeyValueArray` version of residual `styles`.

`residualStyles`:

```
KeyValueArray<any>|undefined|null;
```

A collection of all class static values for an element (including from host). This field will be populated if and when:

- There are one or more initial classes on an element (e.g. `<div class="one two three">`)
- There are one or more initial classes on a directive/component host (e.g. `@Directive({host: {class: "SOME_CLASS" } })`)

`classes`: `string|null`

A collection of all class static values for an element excluding host sources. Populated when there are one or more initial classes on an element (e.g. `<div class="SOME_CLASS">`). Must be stored separately from `tNode.classes` to facilitate setting directive inputs that shadow the `class` property. If we used `tNode.classes` as is for shadowed inputs, we would feed host classes back into directives as `"inputs"`. If we used `tNode.attrs`, we would have to concatenate the attributes on every template pass. Instead, we process once on first create pass and store here.

```
classesWithoutHost: string|null;
```

A `KeyValueArray` version of residual `classes`.

Same as `TNode.residualStyles` but for classes.

`undefined`: not initialized. `null`: initialized but `classes` is `null`.

```
KeyValueArray<any>|undefined|null;
```

Stores the head/tail index of the class bindings.

- If no bindings, the head and tail will both be `0`.
- If there are template bindings, stores the head/tail of the class bindings in the template.
- If no template bindings but there are host bindings, the head value will point to the last host binding for `"class"` (not the head of the linked list), tail will be `0`.

See: `style_binding_list.ts` for details.

This is used by `insertTStylingBinding` to know where the next styling binding should be inserted so that they can be sorted in priority order.

```
classBindings: TStylingRange;
```

Stores the head/tail index of the class bindings.

- If no bindings, the head and tail will both be `0`.
- If there are template bindings, stores the head/tail of the style bindings in the template.
- If no template bindings but there are host bindings, the head value will point to the

```

last * host binding for "style" (not the head of the linked list), tail will be 0. * See:
`style_binding_list.ts` for details. * This is used by `insertTStylingBinding` to know where the next styling
binding should be * inserted so that they can be sorted in priority order. * styleBindings:

      tNode = isProjection ? tNode.projectionNext : tNode.next;
    }
  }
}

```

`applyView` performs operation on the view as specified in `action` (insert, detach, destroy)

Inserting a view without projection or containers at top level is simple. Just iterate over the root nodes of the View, and for each node perform the `action`.

Things get more complicated with containers and projections. That is because coming across:

- Container: implies that we have to insert/remove/destroy the views of that container as well which in turn can have their own Containers at the View roots.
- Projection: implies that we have to insert/remove/destroy the nodes of the projection. The complication is that the nodes we are projecting can themselves have Containers or other Projections.

As you can see this is a very recursive problem. Yes recursion is not most efficient but the code is complicated enough that trying to implemented with recursion becomes unmaintainable.

```

 * @param tView The `TView` which needs to be inserted, detached, destroyed
 * @param IView The LView which needs to be inserted, detached, destroyed.
 * @param renderer Renderer to use
 * @param action action to perform (insert, detach, destroy)
 * @param parentRElement parent DOM element for insertion (Removal does not need it).
 * @param beforeNode Before which node the insertions should happen.
 */
function applyView(
tView: TView, IView: LView, renderer: Renderer3, action:
WalkTreeNodeAction.Destroy, parentRElement: null, beforeNode: null): void;
function applyView(
tView: TView, IView: LView, renderer: Renderer3, action: WalkTreeNodeAction,
parentRElement: RElement|null, beforeNode: RNode|null): void;
function applyView(
tView: TView, IView: LView, renderer:
Renderer3, action: WalkTreeNodeAction,
parentRElement: RElement|null, beforeNode: RNode|null): void {
  applyNodes(renderer, action, tView.firstChild, IView, parentRElement, beforeNode, false);
}

```

`applyProjection` performs operation on the projection.

Inserting a projection requires us to locate the projected nodes from the parent component. The complication is that those nodes themselves could be re-projected from their parent component.

```

 * @param tView The `TView` of `LView` which needs to be inserted,
 detached, destroyed
 * @param IView The `LView` which needs to be inserted, detached, destroyed.
 * @param tProjectionNode node to project
 */
export function applyProjection(tView: TView, IView: LView,
tProjectionNode: TProjectionNode) {
  const renderer = IView[RENDERER];
  const parentRNode =

      executeInitAndCheckHooks(IView, preOrderHooks,
        InitPhaseState.OnInitHooksToBeRun, index);
    }
  }
}

```

We must set the selected index *after* running the hooks, because hooks may have side-effects that cause other template functions to run, thus updating the selected index, which is global state. If we run `setSelectedIndex` *before* we run the hooks, in some cases the selected index will be altered by the time we leave the `advance` instruction.

```

setSelectedIndex(index);\n}\n", "/*\n * @license\n * Copyright Google LLC All Rights Reserved.\n *\n * Use of
this source code is governed by an MIT-style license that can be\n * found in the LICENSE file at
https://angular.io/license\n */\n\nimport { KeyValueArray } from './util/array_utils';\nimport { assertNumber,
assertNumberInRange } from './util/assert';\n\n/**\n * Value stored in the `TData` which is needed to re-
concatenate the styling.\n *\n * See: `TStylingKeyPrimitive` and `TStylingStatic`\n */\nexport type TStylingKey =
TStylingKeyPrimitive|TStylingStatic;\n\n\n/**\n * The primitive portion (`TStylingStatic` removed) of the value
stored in the `TData` which is\n * needed to re-concatenate the styling.\n *\n * - `string`: Stores the property name.
Used with `styleProp`/^`classProp` instruction.\n * - `null`: Represents map, so there is no name. Used with
`styleMap`/^`classMap`\n * - `false`: Represents an ignore case. This happens when `styleProp`/^`classProp`
instruction\n * is combined with directive which shadows its input `@Input('class')`. That way the binding\n *
should not participate in the styling resolution.\n */\nexport type TStylingKeyPrimitive = string|null|false;\n\n\n/**\n * Store the static values for the styling binding.\n *\n * The `TStylingStatic` is just `KeyValueArray` where key `\"\"`
(stored at location 0) contains the\n * `TStylingKey` (stored at location 1). In other words this wraps the
`TStylingKey` such that the\n * `\"\"` contains the wrapped value.\n *\n * When instructions are resolving styling
they may need to look forward or backwards in the linked\n * list to resolve the value. For this reason we have to
make sure that the linked list also contains\n * the static values. However the list only has space for one item per
styling instruction. For this\n * reason we store the static values here as part of the `TStylingKey`. This means that
the\n * resolution function when looking for a value needs to first look at the binding value, and then\n * at
`TStylingKey` (if it exists).\n *\n * Imagine we have:\n *\n * <div class=\"TEMPLATE\" my-dir>\n *\n * @Directive({\n *   host: {\n *     class: 'DIR',\n *     '[class.dynamic]': 'exp' // classProp('dynamic', ctx.exp);\n *   })\n *\n * })\n *\n * In the above case the linked list will contain one item:\n *\n * // assume binding location:
10 for `classProp('dynamic', ctx.exp);\n * tData[10] = <TStylingStatic>[\n *   'dynamic', // This is the wrapped
value of `TStylingKey`\n *   'DIR': true, // This is the default static value of directive binding.\n * ];\n *
tData[10 + 1] = 0; // We don't have prev/next.\n *\n * IView[10] = undefined; // assume `ctx.exp` is
`undefined`\n * IView[10 + 1] = undefined; // Just normalized `IView[10]`\n *\n * So when the function is
resolving styling value, it first needs to look into the linked list\n * (there is none) and then into the static
`TStylingStatic` too see if there is a default value for\n * `dynamic` (there is not). Therefore it is safe to remove it.\n
*\n * If setting `true` case:\n *\n * IView[10] = true; // assume `ctx.exp` is `true`\n * IView[10 + 1] = true; //
Just normalized `IView[10]`\n *\n * So when the function is resolving styling value, it first needs to look into the
linked list\n * (there is none) and then into `TNode.residualClass` (`TNode.residualStyle`) which contains\n *
`TNode.residualClass = [\n *   'TEMPLATE': true,\n * ];\n *\n * This means that it is safe to add class.\n
*/\nexport interface TStylingStatic extends KeyValueArray<any> {} \n\n\n/**\n * This is a branded number which
contains previous and next index.\n *\n * When we come across styling instructions we need to store the
`TStylingKey` in the correct\n * order so that we can re-concatenate the styling value in the desired priority.\n
*\n * The insertion can happen either at the:\n * - end of template as in the case of coming across additional styling
instruction in the template\n * - in front of the template in the case of coming across additional instruction in the
`hostBindings`\n *\n * We use `TStylingRange` to store the previous and next index into the `TData` where the
template\n * bindings can be found.\n *\n * - bit 0 is used to mark that the previous index has a duplicate for current
value.\n * - bit 1 is used to mark that the next index has a duplicate for the current value.\n * - bits 2-16 are used to
encode the next/tail of the template.\n * - bits 17-32 are used to encode the previous/head of template.\n *\n *
NOTE: *duplicate* false implies that it is statically known that this binding will not collide\n * with other bindings
and therefore there is no need to check other bindings. For example the\n * bindings in `<div [style.color]=\"exp\"
[style.width]=\"exp\">` will never collide and will have\n * their bits set accordingly. Previous duplicate means that
we may need to check previous if the\n * current binding is `null`. Next duplicate means that we may need to check
next bindings if the\n * current binding is not `null`.\n *\n * NOTE: `0` has special significance and represents `null`
as in no additional pointer.\n */\nexport interface TStylingRange {\n  __brand__: 'TStylingRange';\n}\n\n\n/**\n * Shift and masks constants for encoding two numbers into and duplicate info into a single number.\n */\nexport const

```

```

hostLView);
const componentTView = componentView[TVIEW];
syncViewWithBlueprint(componentTView,
componentView);
renderView(componentTView, componentView, componentView[CONTEXT]);

```

Syncs an LView instance with its blueprint if they have gotten out of sync. Typically, blueprints and their view instances should always be in sync, so the loop here will be skipped. However, consider this case of two components side-by-side:

App template:

```

<comp>
<comp>

```

The following will happen:

- App template begins processing.
- First <comp> is matched as a component and its LView is created.
- Second <comp> is matched as a component and its LView is created.
- App template completes processing, so it's time to check child templates.
- First <comp> template is checked. It has a directive, so its def is pushed to blueprint.
- Second <comp> template is checked. Its blueprint has been updated by the first <comp> template, but its LView was created before this update, so it is out of sync.

Note that embedded views inside ngFor loops will never be out of sync because these views are processed as soon as they are created.

@param tView The `TView` that contains the blueprint for syncing

@param IView The view to sync

```

function syncViewWithBlueprint(tView: TView, IView: LView) {
  for (let i = IView.length; i < tView.blueprint.length; i++) {
    IView.push(tView.blueprint[i]);
  }
}

```

Adds LView or LContainer to the end of the current view tree. This structure will be used to traverse through nested views to remove listeners and call onDestroy callbacks.

@param IView The view where LView or LContainer should be added

@param adjustedHostIndex Index of the view's host node in LView[], adjusted for header

@param IViewOrLContainer The LView or LContainer to add to the view tree

@returns The state passed in

```

export function addToViewTree<T extends LView|LContainer>(IView: LView, IViewOrLContainer: T): T {
  // TODO(benlesh/misko): This implementation is incorrect, because it always adds the LContainer
  // to the end of the queue, which means if the developer retrieves the LContainers from RNodes out
  // of order, the change detection will run out of order, as the act of retrieving the the
  // LContainer from the RNode is what adds it to the queue.
  if (IView[CHILD_HEAD]) {
    IView[CHILD_TAIL]![NEXT] = IViewOrLContainer;
  } else {
    IView[CHILD_HEAD] = IViewOrLContainer;
  }
  IView[CHILD_TAIL] = IViewOrLContainer;
  return IViewOrLContainer;
}

```

Change detection

Marks current view and all ancestors dirty.

Returns the root view because it is found as a byproduct of marking the view tree dirty, and can be used by methods that consume markViewDirty() to easily schedule change detection. Otherwise, such methods would need to traverse up the view tree an additional time to get the root view and schedule a tick on it.

@param IView The starting LView to mark dirty

@returns the root LView

```

export function markViewDirty(IView: LView): LView|null {
  while (IView) {
    IView[FLAGS] |= LViewFlags.Dirty;
    const parent = getLViewParent(IView);
    // Stop traversing up as soon as you find a root view that wasn't attached to any container
    if (isRootView(IView) && !parent) {
      return IView;
    }
    // continue otherwise
    IView = parent!;
  }
  return null;
}

```

Used to schedule change detection on the whole application. Unlike `tick`, `scheduleTick` coalesces multiple calls into one change detection run. It is usually called indirectly by calling `markDirty` when the view needs to be re-rendered. Typically `scheduleTick` uses `requestAnimationFrame` to coalesce multiple `scheduleTick` requests. The scheduling function can be overridden in `renderComponent`'s `scheduler` option.

```

export function scheduleTick(rootContext: RootContext, flags: RootContextFlags) {
  const nothingScheduled = rootContext.flags === RootContextFlags.Empty;
  if (nothingScheduled && rootContext.clean === _CLEAN_PROMISE) {
    // https://github.com/angular/angular/issues/39296
    // should only attach the flags when really scheduling a tick
    rootContext.flags |= flags;
    let res: null|((val: null) => void);
    rootContext.clean = new Promise<null>((r) => res = r);
    rootContext.scheduler() => {
      if (rootContext.flags & RootContextFlags.DetectChanges) {
        rootContext.flags &= ~RootContextFlags.DetectChanges;
        tickRootContext(rootContext);
      }
      if (rootContext.flags & RootContextFlags.FlushPlayers) {
        rootContext.flags &= ~RootContextFlags.FlushPlayers;
        const playerHandler = rootContext.playerHandler;
        if (playerHandler) {
          playerHandler.flushPlayers();
        }
      }
      rootContext.clean = _CLEAN_PROMISE;
      res!(null);
    };
  }
}

```

export function tickRootContext(rootContext: RootContext) {
 for (let i = 0; i < rootContext.components.length; i++) {
 const rootComponent = rootContext.components[i];
 const IView =

```

 resolving\n * dependencies.\n *\n * An `Injector` is a replacement for a `new` operator, which can automatically
 resolve the\n * constructor dependencies.\n *\n * In typical use, application code asks for the dependencies in the
 constructor and they are\n * resolved by the `Injector`.\n *\n * @usageNotes\n * ### Example\n *\n * The following
 example creates an `Injector` configured to create `Engine` and `Car`.\n *\n * ```typescript\n * @Injectable()\n *
 class Engine {\n * }\n *\n * @Injectable()\n * class Car {\n *   constructor(public engine:Engine) {}\n * }\n *\n *
 var injector = ReflectiveInjector.resolveAndCreate([Car, Engine]);\n * var car = injector.get(Car);\n * expect(car
 instanceof Car).toBe(true);\n * expect(car.engine instanceof Engine).toBe(true);\n * ```\n *\n * Notice, we don't use
 the `new` operator because we explicitly want to have the `Injector` resolve all of the object's dependencies
 automatically.\n *\n * @deprecated from v5 - slow and brings in a lot of code, Use `Injector.create` instead.\n *

residual styling to see if the current `tStylingKey` is duplicate of residual.\n *\n * @param tNode `TNode` where the
residual is stored.\n * @param tStylingKey `TStylingKey` to store.\n * @param tData `TData` associated with the
current `LView`.\n * @param index location of where `tStyleValue` should be stored (and linked into list.)\n *\n * @param isClassBinding True if the associated `tStylingKey` as a `class` styling.\n *\n * `tNode.classBindings` should be used (or `tNode.styleBindings` otherwise.)\n */\nfunction
markDuplicateOfResidualStyling(\n tNode: TNode, tStylingKey: TStylingKey, tData: TData, index: number,
isClassBinding: boolean) {\n const residual = isClassBinding ? tNode.residualClasses : tNode.residualStyles;\n if
(residual != null /* or undefined */ && typeof tStylingKey === 'string' &&\n keyValueArrayIndexOf(residual,
tStylingKey) >= 0) {\n // We have duplicate in the residual so mark ourselves as duplicate.\n tData[index + 1] =
setTStylingRangeNextDuplicate(tData[index + 1] as TStylingRange);\n }\n}\n\n/**\n * Marks `TStyleValue`s as
duplicates if another style binding in the list has the same\n * `TStyleValue`.\n *\n * NOTE: this function is
intended to be called twice once with `isPrevDir` set to `true` and once\n * with it set to `false` to search both the
previous as well as next items in the list.\n *\n * No duplicate case\n * ```\n * [style.color]\n * [style.width.px]
<<- index\n * [style.height.px]\n * ```\n *\n * In the above case adding `[style.width.px]` to the existing
`[style.color]` produces no\n * duplicates because `width` is not found in any other part of the linked list.\n *\n * Duplicate case\n * ```\n * [style.color]\n * [style.width.em]\n * [style.width.px] <<- index\n * ```\n *\n * In the
above case adding `[style.width.px]` will produce a duplicate with `[style.width.em]`\n * because `width` is found in
the chain.\n *\n * Map case 1\n * ```\n * [style.width.px]\n * [style.color]\n * [style] <<- index\n * ```\n *\n * In the
above case adding `[style]` will produce a duplicate with any other bindings because\n * `[style]` is a Map and as

```

such is fully dynamic and could produce `color` or `width`.  
 In the above case adding `[style.color]` will produce a duplicate because there is already a `[style]` binding which is a Map and as such is fully dynamic and could produce `color` or `width`.  
 NOTE: Once `[style]` (Map) is added into the system all things are mapped as duplicates.  
 NOTE: We use `style` as example, but same logic is applied to `classes` as well.  
 @param tData `TData` where the linked list is stored.  
 @param tStylingKey `TStylingKeyPrimitive` which contains the value to compare to other keys in the linked list.  
 @param index Starting location in the linked list to search from  
 @param isPrevDir Direction. - `true` for previous (lower priority); - `false` for next (higher priority).

```

}
}

Retrieve the `TStylingKey` for the template styling instruction.
This is needed since `hostBinding` styling
instructions are inserted after the template
instruction. While the template instruction needs to update the
residual in `TNode` the `hostBinding` instructions need to update the `TStylingKey` of the template instruction
because the template instruction is downstream from the `hostBindings` instructions.
@param tData `TData` where the linked list is stored.
@param tNode `TNode` for which the styling is being computed.
@param isClassBased `true` if `class` (`false` if `style`)
@return `TStylingKey` if found or `undefined` if not
found.
}

function getTemplateHeadTStylingKey(tData: TData, tNode: TNode, isClassBased: boolean):
TStylingKey {
 if (undefined) {

 if (getTStylingRangeNext(bindings) === 0) {
 // There does not seem to be a styling instruction in the `template`.
 return undefined;
 }
 return tData[getTStylingRangePrev(bindings)] as TStylingKey;
 }
 // Update the
 `TStylingKey` of the first template instruction in `TNode`.
 // Logically `hostBindings` styling instructions are
 of lower priority than that of the template.
 // However, they execute after the template styling instructions. This
 means that they get inserted
 // in front of the template styling instructions.
 // If we have a template styling
 instruction and a new `hostBindings` styling instruction is
 // executed it means that it may need to steal static fields
 from the template instruction. This
 // method allows us to update the first template instruction `TStylingKey` with
 a new value.
 // Assume:
 <div my-dir style="color: red" [style.color]="tmplExp"></div>
 @Directive({
 host: {
 'style': 'width: 100px',
 [style.color]: 'dirExp',
 }
 })
 class MyDir
 {
 when [style.color]="tmplExp"
 executes it creates this data structure:
 ['color',
 'color', 'red', 'width', '100px'],
 // The reason for this is that the template instruction does not know if there
 are styling
 // instructions and must assume that there are none and must collect all of the static styling.
 // (both
 // `color` and `width`)
 // When `[style.color]: 'dirExp',` executes we need to insert a new data into the linked
 list.
 ['color', 'width', '100px'], // newly inserted
 ['color', 'color', 'red', 'width', '100px'], // this is
 wrong
 // Notice that the template statics is now wrong as it incorrectly contains `width` so we need to
 // update it like so:
 ['color', 'width', '100px'],
 ['color', 'color', 'red'], // UPDATE
 }
 @param tData `TData` where the linked list is stored.

comment (rather than a text) node.\n */\n COMMENT = 0b10,\n}\n\n/**\n * Stores DOM operations which
need to be applied to update DOM render tree due to changes in\n * expressions.\n *\n * The basic idea is that
`i18nExp` OpCodes capture expression changes and update a change\n * mask bit. (Bit 1 for expression 1, bit 2 for
expression 2 etc..., bit 32 for expression 32 and\n * higher.) The OpCodes then compare its own change mask
against the expression change mask to\n * determine if the OpCodes should execute.\n *\n * NOTE: 32nd bit is
special as it says 32nd or higher. This way if we have more than 32 bindings\n * the code still works, but with lower
efficiency. (it is unlikely that a translation would have\n * more than 32 bindings.)\n *\n * These OpCodes can be
used by both the i18n block as well as ICU sub-block.\n *\n * ## Example\n *\n * Assume\n * ```ts\n * if (rf &
RenderFlags.Update) {\n *  i18nExp(ctx.exp1); // If changed set mask bit 1\n *  i18nExp(ctx.exp2); // If changed
set mask bit 2\n *  i18nExp(ctx.exp3); // If changed set mask bit 3\n *  i18nExp(ctx.exp4); // If changed set mask
bit 4\n *  i18nApply(0); // Apply all changes by executing the OpCodes.\n * }\n * ```\n *\n * We can assume
that each call to `i18nExp` sets an internal `changeMask` bit depending on the\n * index of `i18nExp`.\n *\n * ###
OpCodes\n * ```ts\n * <I18nUpdateOpCodes>[\n * // The following OpCodes represent: <div i18n-
title=\"pre { {exp1} } in { {exp2} } post\">\n * // If `changeMask & 0b11`\n * // has changed then execute update
OpCodes.\n * // has NOT changed then skip `8` values and start processing next OpCodes.\n * 0b11, 8,\n * //
Concatenate `newValue = 'pre'+IView[bindIndex-4]+'in'+IView[bindIndex-3]+'post';`. \n * 'pre', -4, 'in', -3,
'post', \n * // Update attribute: `elementAttribute(1, 'title', sanitizerFn(newValue));`\n * 1 << SHIFT_REF | Attr,
'title', sanitizerFn, \n * // The following OpCodes represent: <div i18n>Hello { {exp3} }!`\n * // If
`changeMask & 0b100`\n * // has changed then execute update OpCodes.\n * // has NOT changed then
skip `4` values and start processing next OpCodes.\n * 0b100, 4,\n * // Concatenate `newValue = 'Hello ' +
IView[bindIndex -2] + '!`;`. \n * 'Hello ', -2, '!', \n * // Update text: `IView[1].textContent = newValue;`\n * 1 <<
SHIFT_REF | Text, \n * // The following OpCodes represent: <div i18n>{exp4, plural, ...}`\n * // If
`changeMask & 0b1000`\n * // has changed then execute update OpCodes.\n * // has NOT changed then

```

`tNode` to `previousTNodes` list and update relevant `TNode`s in `previousTNodes` list\n *  

`TNode.insertBeforeIndex`.\n * See\n * Things to keep in mind:\n * 1. All i18n text nodes are encoded as\n
`TNodeType.Element` and are created eagerly by the\n * `i18nStart` instruction.\n * 2. All\n
`TNodeType.Placeholder` `TNodes` are elements which will be created later by\n * `elementStart` instruction.\n *  

3. `elementStart` instruction will create `TNode`s in the ascending `TNode.index` order. (So a\n * smaller index\n
`TNode` is guaranteed to be created before a larger one)\n * We use the above three invariants to determine\n
`TNode.insertBeforeIndex`.\n * In an ideal world `TNode.insertBeforeIndex` would always be\n
`TNode.next.index`. However,\n * this will not work because `TNode.next.index` may be larger than `TNode.index`\n
which means that\n * the next node is not yet created and therefore we can't insert in front of it.\n * Rule1:\n
`TNode.insertBeforeIndex = null` if `TNode.next === null` (Initial condition, as we don't\n * know if there will\n
be further `TNode`s inserted after.)\n * Rule2: If `previousTNode` is created after the `tNode` being inserted, then\n
*\n * `previousTNode.insertBeforeIndex = tNode.index` (So when a new `tNode` is added we check\n *  

previous to see if we can update its `insertBeforeIndex`)\n * See `TNode.insertBeforeIndex` for more\n
context.\n * @param previousTNodes A list of previous TNodes so that we can easily traverse `TNode`s in\n *

* Marks a block of text as translatable.

* The instructions `i18nStart` and `i18nEnd` mark the translation block in the template.

* The translation `message` is the value which is locale specific. The translation string may contain placeholders which associate inner elements and sub-templates within the translation.

* The translation `message` placeholders are:

- `{index}({block})`: **Binding Placeholder**: Marks a location where an expression will be interpolated into. The placeholder `index` points to the expression binding index. An optional `block` that matches the sub-template in which it was declared.
- `#{index}({block})^/#{index}({block})`: **Element Placeholder**: Marks the beginning and end of DOM element that were embedded in the original translation block. The placeholder `index` points to the element index in the template instructions set. An optional `block` that matches the sub-template in which it was declared.
- `*{index}({block})^/*{index}({block})`: **Sub-template Placeholder**: Sub-templates must be split up and translated separately in each angular template function. The `index` points to the `template` instruction index. A `block` that matches the sub-template in which it was declared.

* `@param index` A unique index of the translation in the static block.

* `@param messageIndex` An index of the translation message from the `def.consts` array.

* `@param subTemplateIndex` Optional sub-template index in the `message`.

```

@codeGenApi
export function i18nStart(index: number, messageIndex: number, subTemplateIndex: number = -1): void {
  const tView = getTView();
  const lView = getLView();
  const adjustedIndex = HEADER_OFFSET + index;
  const ngDevMode = true;
  const assertDefined = (tView, `tView should be defined`);
  const message = getConstant<string>(tView.consts, messageIndex);
  const parentTNode = getCurrentParentTNode() as TElementNode | null;
  if (tView.firstCreatePass) {
    i18nStartFirstCreatePass(tView, parentTNode === null ? 0 : parentTNode.index, lView, adjustedIndex, message, subTemplateIndex);
  }
  const t18n = tView.data[adjustedIndex] as T18n;
  const sameViewParentTNode = parentTNode === lView[T_HOST] ? null : parentTNode;
  const parentRNode = getClosestRElement(tView, sameViewParentTNode, lView);
  // If `parentTNode` is an `ElementContainer` then it has `<!--ng-container-->`.
  // When we do inserts we have to make sure to insert in front of `<!--ng-container-->`.
  const insertInFrontOf = parentTNode && (parentTNode.type & TNodeType.ElementContainer) ? lView[parentTNode.index] : null;
  applyCreateOpCodes(lView, t18n.create, parentRNode, insertInFrontOf);
  setInI18nBlock(true);
}

```

* Translates a translation block marked by `i18nStart` and `i18nEnd`. It inserts the text/ICU nodes into the render tree, moves the placeholder nodes and removes the deleted nodes.

* `@codeGenApi`

```

export function i18nEnd(): void {
  setInI18nBlock(false);
}

```

* Use this instruction to create a translation block that doesn't contain any placeholder.

* It calls both `{@link i18nStart}` and `{@link i18nEnd}` in one instruction.

* The translation `message` is the value which is locale specific. The translation string may contain placeholders which associate inner elements and sub-templates within the translation.

* The translation `message` placeholders are:

- `{index}({block})`: **Binding Placeholder**: Marks a location where an expression will be interpolated into. The placeholder `index` points to the expression binding index. An optional `block` that matches the sub-template in which it was declared.
- `#{index}({block})^/#{index}({block})`: **Element Placeholder**: Marks the beginning and end of DOM element that were embedded in the original translation block. The placeholder `index` points to the element index in the template instructions set. An optional `block` that matches the sub-template in which it was declared.
- `*{index}({block})^/*{index}({block})`: **Sub-template Placeholder**: Sub-templates must be

split up and translated separately in each angular template function. The `index` points to the `template` instruction index. A `block` that matches the sub-template in which it was declared.

`@param index` A unique index of the translation in the static block.

`@param messageIndex` An index of the translation message from the `def.consts` array.

`@param subTemplateIndex` Optional sub-template index in the `message`.

`@codeGenApi` `export function i18n(index: number, messageIndex: number, subTemplateIndex?: number): void {`

`i18nStart(index, messageIndex, subTemplateIndex);`

`i18nEnd();`

`}`

`/**` Marks a list of attributes as translatable.

`@param index` A unique index in the static block

`@param values`

`@codeGenApi` `export function i18nAttributes(index: number, attrsIndex: number): void {`

`const tView = getTView();`

`ngDevMode && assertDefined(tView, `tView should be defined`);`

`const attrs = getConstant<string[]>(tView.consts, attrsIndex!);`

`i18nAttributesFirstPass(tView, index + HEADER_OFFSET, attrs);`

`}`

`/**` Stores the values of the bindings during each update cycle in order to determine if we need to update the translated nodes.

`@param value` The binding's value

`@returns` This function returns itself so that it may be chained (e.g. `i18nExp(ctx.name)(ctx.title)`)

`@codeGenApi` `export function i18nExp<T>(value: T): typeof i18nExp {`

`const IView = getLView();`

`setMaskBit(bindingUpdated(IView, nextBindingIndex(), value));`

`return i18nExp;`

`}`

`/**` Updates a translation block or an i18n attribute when the bindings have changed.

`@param index` Index of either { @link i18nStart } (translation block) or { @link i18nAttributes } (i18n attribute) on which it should update the content.

`@codeGenApi` `export function i18nApply(index: number) {`

`applyI18n(getTView(), getLView(), index + HEADER_OFFSET);`

`}`

`/**` Handles message string post-processing for internationalization.

`Handles message string post-processing by transforming it from intermediate format (that might contain some markers that we need to replace) to the final form, consumable by i18nStart instruction. Post processing steps include:`

1. Resolve all multi-value cases (like `[*1:#2:1|#4:1|5]`)
2. Replace all ICU vars (like `"VAR_PLURAL"`)
3. Replace all placeholders used inside ICUs in a form of `{PLACEHOLDER}`
4. Replace all ICU references with corresponding values (like `ICU_EXP_ICU_1`) in case multiple ICUs have the same placeholder name

`@param message` Raw translation string for post processing

`@param replacements` Set of replacements that should be applied

`@returns` Transformed string that can be consumed by i18nStart instruction

`@codeGenApi` `export function i18nPostprocess(message: string, replacements: {[key: string]: (string|string[])} = {}): string {`

`return i18nPostprocess(message, replacements);`

`}`

`/**` This file re-exports all symbols contained in this directory.

`Why is this file not `index.ts`?`

`There seems to be an inconsistent path resolution of an `index.ts` file when only the parent directory is referenced. This could be due to the node module resolution configuration differing from rollup and/or typescript.`

`With commit https://github.com/angular/angular/commit/d5e3f2c64bd13ce83e7c70788b7fc514ca4a9918 the `instructions.ts` file was moved to `instructions/instructions.ts` and an `index.ts` file was used to re-export everything. Having had file names that were importing from `instructions` directly (not the from the sub file or the `index.ts` file) caused strange CI issues. `index.ts` had to be renamed to `all.ts` for this to work.`

of its ancestors dirty.\n  * It also triggers change detection by calling `scheduleTick` internally, which
coalesces\n  * multiple `markForCheck` calls to into one change detection run.\n  * This can be used to ensure
an { @link ChangeDetectionStrategy#OnPush OnPush} component is\n  * checked when it needs to be re-rendered
but the two normal triggers haven't marked it\n  * dirty (i.e. inputs haven't changed and events haven't fired in the
view).\n  * <!-- TODO: Add a link to a chapter on OnPush components -->\n  * @usageNotes\n  * ###
Example\n  * ```typescript\n  * @Component({\n  *   selector: 'my-app',\n  *   template: `Number of ticks:
{{numberOfTicks}}`\n  *   changeDetection: ChangeDetectionStrategy.OnPush,\n  * })\n  * class AppComponent
{\n  *   numberOfTicks = 0;\n  *   constructor(private ref: ChangeDetectorRef) {\n  *     setInterval(() => {\n
*     this.numberOfTicks++;\n  *     // the following is required, otherwise the view will not be updated\n  *
this.ref.markForCheck();\n  *     }, 1000);\n  *   }\n  * }\n  * ```\n  * \n  * markForCheck(): void {\n
markViewDirty(this._cdRefInjectingView || this._IView);\n  }\n}\n\n /**\n  * Detaches the view from the change
detection tree.\n  * Detached views will not be checked during change detection runs until they are\n  * re-
attached, even if they are dirty. `detach` can be used in combination with\n  * { @link
ChangeDetectorRef#detectChanges detectChanges} to implement local change\n  * detection checks.\n  * <!--
TODO: Add a link to a chapter on detach/reattach/local digest -->\n  * <!-- TODO: Add a live demo once
ref.detectChanges is merged into master -->\n  * @usageNotes\n  * ### Example\n  * \n  * The following
example defines a component with a large list of readonly data.\n  * Imagine the data changes constantly, many
times per second. For performance reasons,\n  * we want to check and update the list every five seconds. We can do
that by detaching\n  * the component's change detector and doing a local check every five seconds.\n  * \n  *
```typescript\n  * class DataProvider {\n  *   // in a real application the returned data will be different every time\n
* get data() {\n * return [1,2,3,4,5];\n * }\n * }\n * \n * @Component({\n * selector: 'giant-list',\n *
template: `\n * <li *ngFor="let d of dataProvider.data">Data {{d}}\n * `,\n * })\n * class GiantList
{\n * constructor(private ref: ChangeDetectorRef, private dataProvider: DataProvider) {\n * ref.detach();\n *
setInterval(() => {\n * this.ref.detectChanges();\n * }, 5000);\n * }\n * }\n * \n * @Component({\n
* selector: 'app',\n * providers: [DataProvider],\n * template: `\n * <giant-list><giant-list>\n * `,\n *
})\n * class App {\n * }\n * }\n * \n * \n * detach(): void {\n * this._IView[FLAGS] &= ~LViewFlags.Attached;\n
}\n}\n\n /**\n * Re-attaches a view to the change detection tree.\n * This can be used to re-attach views that
were previously detached from the tree\n * using { @link ChangeDetectorRef#detach detach}. Views are attached
to the tree by default.\n * <!-- TODO: Add a link to a chapter on detach/reattach/local digest -->\n * \n *
@usageNotes\n * ### Example\n * \n * The following example creates a component displaying `live` data. The
component will detach\n * its change detector from the main change detector tree when the component's live
property\n * is set to false.\n * \n * ```typescript\n * class DataProvider {\n * data = 1;\n * \n *
constructor() {\n * setInterval(() => {\n * this.data = this.data * 2;\n * }, 500);\n * }\n * }\n * \n *
@Component({\n * selector: 'live-data',\n * inputs: ['live'],\n * template: 'Data: {{dataProvider.data}}'\n *
})\n * class LiveData {\n * constructor(private ref: ChangeDetectorRef, private dataProvider: DataProvider) {\n *
*\n * set live(value) {\n * if (value) {\n * this.ref.reattach();\n * } else {\n * this.ref.detach();\n
*\n * }\n * }\n * }\n * \n * @Component({\n * selector: 'my-app',\n * providers: [DataProvider],\n *
template: `\n * Live Update: <input type="checkbox" [(ngModel)]="live">\n * <live-data
[live]="live"><live-data>\n * `,\n * })\n * class AppComponent {\n * live = true;\n * }\n * }\n * \n * \n *
reattach(): void {\n * this._IView[FLAGS] |= LViewFlags.Attached;\n * }\n}\n\n /**\n * Checks the view and its
children.\n * This can also be used in combination with { @link ChangeDetectorRef#detach detach} to
implement\n * local change detection checks.\n * <!-- TODO: Add a link to a chapter on

```

```

 }
 // This function calls the ngAfterContentCheck, ngAfterContentInit,
 ngAfterViewCheck,
 and ngAfterViewInit lifecycle hooks (depending on the node
 flags in lifecycle). Unlike ngDoCheck,
 ngOnChanges and ngOnInit, which are
 called during a pre-order traversal of the view tree (that is calling the
 parent hooks before the child hooks) these events are sent in using a
 post-order traversal of the tree (children
 before parents). This changes the
 meaning of initIndex in the view state. For ngOnInit, initIndex tracks the
 expected nodeIndex which a ngOnInit should be called. When sending
 ngAfterContentInit and ngAfterViewInit
 it is the expected count of
 ngAfterContentInit or ngAfterViewInit methods that have been called. This
 ensure
 that despite being called recursively or after picking up after an
 exception, the ngAfterContentInit or
 ngAfterViewInit will be called on the
 correct nodes. Consider for example, the following (where E is an
 element
 and D is a directive)
 Tree:
 pre-order index post-order index
 E1 0 6 E2
 1 1 D3 2 0 E4 3 5 E5 4 4 E6 5
 2 E7 6 3
 As can be seen, the post-order index has an unclear relationship to the
 pre-order
 index (postOrderIndex === preOrderIndex - parentCount + childCount).
 Since number of calls to
 ngAfterContentInit and ngAfterViewInit
 are stable (will be the same for the same view regardless of exceptions
 or
 recursion) we just need to count them which will roughly correspond to the
 post-order
 index (it skips
 elements and directives that do not have
 lifecycle hooks).
 For example, if an exception is raised in the
 E6.onAfterViewInit() the
 initIndex is left at 3 (by shouldCallLifecycleInitHook() which set it to
 initIndex +
 1). When checkAndUpdateView() is called again D3, E2 and E6 will
 not have their ngAfterViewInit() called but,
 starting with E7, the rest of
 the view will begin getting ngAfterViewInit() called until a check and
 pass is
 complete.
 This algorithm also handles recursion. Consider if E4's ngAfterViewInit()
 indirectly calls E1's
 ChangeDetectorRef.detectChanges(). The expected
 initIndex is set to 6, the recursive checkAndUpdateView()
 starts walk again.
 D3, E2, E6, E7, E5 and E4 are skipped, ngAfterViewInit() is called on E1.
 When the
 recursion returns the initIndex will be 7 so E1 is skipped as it
 has already been called in the recursively called
 checkAnUpdateView().

timing) of\n // this call is critical to ensure this works correctly (modules get registered when expected)\n // without bloating bundles (modules are registered when otherwise not referenced).\n //\n // In View Engine,
registration occurs in the .ngfactory.js file as a side effect. This has\n // several practical consequences:\n //\n // - If an .ngfactory file is not imported from, the module won't be registered (and can be\n // tree shaken).\n // - If an .ngfactory file is imported from, the module will be registered even if an instance\n // is not actually
created (via `create` below).\n // - Since an .ngfactory file in View Engine references the .ngfactory files of the
NgModule's\n // imports,\n //\n // In Ivy, things are a bit different. .ngfactory files still exist for
compatibility, but are\n // not a required API to use - there are other ways to obtain an NgModuleFactory for a
given\n // NgModule. Thus, relying on a side effect in the .ngfactory file is not sufficient. Instead,\n // the side
effect of registration is added here, in the constructor of NgModuleFactory,\n // ensuring no matter how a factory
is created, the module is registered correctly.\n //\n // An alternative would be to include the registration side
effect inline following the actual\n // NgModule definition. This also has the correct timing, but breaks tree-
shaking - modules\n // will be registered and retained even if they're otherwise never referenced.\n }\n registerNgModuleType(moduleType as NgModuleType);\n }\n\n create(parentInjector: Injector|null):

```

that marks a class as an Angular directive.

- You can define your own directives to attach custom behavior to elements in the DOM.
- The options provide configuration metadata that determines how the directive should be processed, instantiated and used at runtime.
- Directive classes, like component classes, can implement [life-cycle hooks](guide/lifecycle-hooks) to influence their configuration and behavior.

`@usageNotes`

To define a directive, mark the class with the decorator and provide metadata.

```
import {Directive} from '@angular/core';
@Directive({
 selector: 'my-directive',
})
export class MyDirective {
 ...
}
Declaring directives
Directives are [declarables](guide/glossary#declarable). They must be declared by an NgModule in order to be usable in an app. A directive must belong to exactly one NgModule. Do not re-declare a directive imported from another module. List the directive class in the `declarations` field of an NgModule.
```

```
declarations: [AppComponent, MyDirective],
@Annotation
(obj?: Directive): TypeDecorator;
/** See the `Directive` decorator.
 new(obj?: Directive):
 Directive;
}
Directive decorator and metadata.
@Annotation
@publicApi
export interface Directive {
 /** The CSS selector that identifies this directive in a template and triggers instantiation of the directive.
 Declare as one of the following:
 * - `element-name`: Select by element name.
 * - `.class`: Select by class name.
 * - `[attribute]`: Select by attribute name.
 * - `[attribute=value]`: Select by attribute name and value.
 * - `:not(sub_selector)`: Select only if the element does not match the `sub_selector`.
 * - `selector1, selector2`: Select if either `selector1` or `selector2` matches.
 Angular only allows directives to apply on CSS selectors that do not cross element boundaries.
 For the following template HTML, a directive with an `input[type=text]` selector, would be instantiated only on the
 <input type="text"> element.
 html
 <form>
 <input type="text">
 <input type="radio">
 <form>
 selector?: string;
 /** Enumerates the set of data-bound input properties for a directive
 Angular automatically updates input properties during change detection.
 The `inputs` property defines a set of `directiveProperty` to `bindingProperty` configuration:
 - `directiveProperty` specifies the component property where the value is written.
 - `bindingProperty` specifies the DOM property where the value is read from.
 When `bindingProperty` is not provided, it is assumed to be equal to `directiveProperty`.
 @usageNotes
 The following example creates a component with two data-bound properties.
 typescript
 @Component({
 selector: 'bank-account',
 inputs: ['bankName', 'id: account-id'],
 template: `
 Bank Name: {{bankName}}
 Account Id: {{id}}
 `
 })
 class BankAccount {
 bankName: string;
 id: string;
 }
 /** Enumerates the set of event-bound output properties.
 When an output property emits an event, an event handler attached to that event in the template is invoked.
 The `outputs` property defines a set of `directiveProperty` to `bindingProperty` configuration:
 - `directiveProperty` specifies the component property that emits events.
 - `bindingProperty` specifies the DOM property the event handler is attached to.
 @usageNotes
 typescript
 @Component({
 selector: 'child-dir',
 outputs: ['bankNameChange']
 })
 class ChildDir {
 bankNameChange: EventEmitter<string> = new EventEmitter<string>();
 }
 @Component({
 selector: 'main',
 template: `
 {{bankName}} <child-dir (bankNameChange)="onBankNameChange($event)"></child-dir>
 `
 })
 class MainComponent {
 bankName: string;
 onBankNameChange(bankName: string) {
 this.bankName = bankName;
 }
 }
 /** Configures the [injector](guide/glossary#injector) of this directive or component with a [token](guide/glossary#di-token) that maps to a [provider](guide/glossary#provider) of a dependency.
 providers?: Provider[];
 /** Defines the name that can be used in the template to assign this directive to a variable.
 @usageNotes
 ts
 @Directive({
 selector: 'child-dir',
 exportAs: 'child'
 })
 class ChildDir {
 }
 @Component({
 selector: 'main',
 template: `<child-dir #c="child"></child-dir>`
 })
 class MainComponent {
 }
 /** Configures the queries that will be injected into the directive.
 Content
```

queries are set before the `ngAfterContentInit` callback is called.

View queries are set before the `ngAfterViewInit` callback is called.

`@usageNotes`

The following example shows how queries are defined and when their results are available in lifecycle hooks:

```

@Component({
 selector: 'someDir',
 queries: {
 contentChildren: new ContentChildren(ChildDirective),
 viewChildren: new ViewChildren(ChildDirective)
 },
 template: '<child-directive></child-directive>'
})
class SomeDir {
 contentChildren: QueryList<ChildDirective>;
 viewChildren: QueryList<ChildDirective>;

 ngAfterContentInit() {
 // contentChildren is set
 }

 ngAfterViewInit() {
 // viewChildren is set
 }
}

```

`@Annotation`

`queries?:` `{[key: string]: any};`

Maps class properties to host element bindings for properties, attributes, and events, using a set of key-value pairs.

Angular automatically checks host property bindings during change detection.

If a binding changes, Angular updates the directive's host element.

When the key is a property of the host element, the property value is propagated to the specified DOM property.

When the key is a static attribute in the DOM, the attribute value is propagated to the specified property in the host element.

For event handling:

- The key is the DOM event that the directive listens to.
- To listen to global events, add the target to the event name.
- The target can be `'window'`, `'document'` or `'body'`.
- The value is the statement to execute when the event occurs. If the statement evaluates to `'false'`, then `preventDefault` is applied on the DOM event. A handler method can refer to the `$event` local variable.

`host?:` `{[key: string]: string};`

When present, this directive/component is ignored by the AOT compiler. It remains in distributed code, and the JIT compiler attempts to compile it at run time, in the browser.

To ensure the correct behavior, the app must import `@angular/compiler`.

`jit?:` `true;`

Type of the Directive metadata.

`@publicApi`

`export const Directive:`

```

DirectiveDecorator = makeDecorator(
 'Directive', (dir: Directive = {}) => dir, undefined, undefined,
 (type: Type<any>, meta: Directive) => SWITCH_COMPILE_DIRECTIVE(type, meta));

```

Component decorator interface

`@publicApi`

`export interface ComponentDecorator` {

Decorator that marks a class as an Angular component and provides configuration metadata that determines how the component should be processed, instantiated, and used at runtime.

Components are the most basic UI building block of an Angular app.

An Angular app contains a tree of Angular components.

Angular components are a subset of directives, always associated with a template.

Unlike other directives, only one component can be instantiated for a given element in a template.

A component must belong to an `NgModule` in order for it to be available to another component or application. To make it a member of an `NgModule`, list it in the `declarations` field of the `NgModule` metadata.

Note that, in addition to these options for configuring a directive, you can control a component's runtime behavior by implementing life-cycle hooks. For more information, see the [\[Lifecycle Hooks\]\(guide/lifecycle-hooks\) guide](#).

`@usageNotes`

### Setting component inputs

The following example creates a component with two data-bound properties, specified by the `inputs` value.

```

<code-example path="core/ts/metadata/directives.ts"
region="component-input"></code-example>

```

### Setting component outputs

The following example shows two event emitters that emit on an interval. One emits an output every second, while the other emits every five seconds.

```

{
 @example core/ts/metadata/directives.ts region="component-output-interval"
}

```

### Injecting a class with a view provider

The following simple example injects a class into a component using the view provider specified in component metadata:

```

class Greeter {
 greet(name:string) {
 return 'Hello ' + name + '!';
 }
}

@Directive({
 selector: 'needs-greeter'
})
class NeedsGreeter {
 greeter:Greeter;

 constructor(greeter:Greeter) {
 this.greeter = greeter;
 }
}

@Component({
 selector: 'greet',
 viewProviders: [
 Greeter
],
 template: '<needs-greeter></needs-greeter>'
})
class HelloWorld {
}

```

### Preserving whitespace

Removing whitespace can greatly reduce AOT-generated code size and speed up view creation.

As of Angular 6, the default for `preserveWhitespaces` is `false` (whitespace is removed).

To change the default setting for all components in your application, set the `preserveWhitespaces` option of the AOT compiler.

By default, the AOT

superfluous whitespace characters from the compiled template. Whitespace characters are those matching the `\s` character class in JavaScript regular expressions. Default is false, unless overridden in compiler options.

`preserveWhitespaces?: boolean;`

`Component decorator and metadata.`

Imports, Exports> = NgModuleDef<T>;\n\n/**\n * A wrapper around an NgModule that associates it with
[providers](guide/glossary#provider\n * \"Definition\"). Usage without a generic type is deprecated.\n * \n * @see
[Deprecations](guide/deprecations#modulewithproviders-type-without-a-generic)\n * \n * @publicApi\n * \nexport
interface ModuleWithProviders<T> {\n ngModule: Type<T>;\n providers?: Provider[];\n}\n\n/**\n * Type of
the NgModule decorator / constructor function.\n * \n * @publicApi\n * \nexport interface NgModuleDecorator {\n
/**\n * Decorator that marks a class as an NgModule and supplies configuration metadata.\n * \n (obj?:
NgModule): TypeDecorator;\n new(obj?: NgModule): NgModule;\n}\n\n/**\n * Type of the NgModule
metadata.\n * \n * @publicApi\n * \nexport interface NgModule {\n /**\n * The set of injectable objects that are
available in the injector\n * of this module.\n * \n * @see [Dependency Injection guide](guide/dependency-
injection)\n * @see [NgModule guide](guide/providers)\n * \n * @usageNotes\n * \n * Dependencies whose
providers are listed here become available for injection\n * into any component, directive, pipe or service that is a
child of this injector.\n * \n * The NgModule used for bootstrapping uses the root injector, and can provide
dependencies\n * to any part of the app.\n * \n * A lazy-loaded module has its own injector, typically a child of
the app root injector.\n * \n * Lazy-loaded services are scoped to the lazy-loaded module's injector.\n * \n * If a lazy-
loaded module also provides the `UserService`, any component created\n * within that module's context (such as
by router navigation) gets the local instance\n * of the service, not the instance in the root injector.\n * \n
Components in external modules continue to receive the instance provided by their injectors.\n * \n * ###
Example\n * \n * The following example defines a class that is injected in\n * the HelloWorld NgModule:\n * \n
* ``\n * class Greeter {\n * greet(name:string) {\n * return 'Hello ' + name + '!';\n * }\n * }\n * \n *
@NgModule({\n * providers: [\n * Greeter\n *]\n * })\n * class HelloWorld {\n * greeter:Greeter;\n
* \n * constructor(greeter:Greeter) {\n * this.greeter = greeter;\n * }\n * }\n * ``\n * \n\n providers?:
Provider[];\n\n/**\n * The set of components, directives, and pipes ([declarables](guide/glossary#declarable))\n
* that belong to this module.\n * \n * @usageNotes\n * \n * The set of selectors that are available to a template
include those declared here, and\n * those that are exported from imported NgModules.\n * \n * Declarables must
belong to exactly one module.\n * \n * The compiler emits an error if you try to declare the same class in more than one
module.\n * \n * Be careful not to declare a class that is imported from another module.\n * \n * ### Example\n * \n
* The following example allows the CommonModule to use the `NgFor`\n * directive.\n * \n * ``javascript\n *
@NgModule({\n * declarations: [NgFor]\n * })\n * class CommonModule {\n * }\n * ``\n * \n\n declarations?: Array<Type<any>|any[]>;\n\n /**\n * The set of NgModules whose exported
[declarables](guide/glossary#declarable)\n * are available to templates in this module.\n * \n * @usageNotes\n
* \n * A template can use exported declarables from any\n * imported module, including those from modules that
are imported indirectly\n * and re-exported.\n * \n * For example, `ModuleA` imports `ModuleB`, and also exports\n
* it, which makes the declarables from `ModuleB` available\n * wherever `ModuleA` is imported.\n * \n * ###
Example\n * \n * The following example allows MainModule to use anything exported by\n *
`CommonModule`:\n * \n * ``javascript\n * @NgModule({\n * imports: [CommonModule]\n * })\n * class
MainModule {\n * }\n * ``\n * \n\n imports?: Array<Type<any>|ModuleWithProviders<{}>|any[]>;\n\n
/**\n * The set of components, directives, and pipes declared in this\n * NgModule that can be used in the
template of any component that is part of an\n * NgModule that imports this NgModule. Exported declarations are
the module's public API.\n * \n * A declarable belongs to one and only one NgModule.\n * \n * A module can list
another module among its exports, in which case all of that module's\n * public declaration are exported.\n * \n *

```

{global} from './util/global';\nimport {getNativeRequestAnimationFrame} from './util/raf';\n\n/**\n * An

```

injectable service for executing work inside or outside of the Angular zone.  
 The most common use of this service is to optimize performance when starting a work consisting of one or more asynchronous tasks that don't require UI updates or error handling to be handled by Angular. Such tasks can be kicked off via `{ @link #runOutsideAngular}` and if needed, these tasks can reenter the Angular zone via `{ @link #run}`.  
 TODO: add/fix links to - docs explaining zones and the use of zones in Angular and change-detection - link to runOutsideAngular/run (throughout this file!)  
 --  
 @usageNotes  
 #### Example  
 ```  
 import { Component, NgZone } from '@angular/core';
 import { NgIf } from '@angular/common';
 @Component({
 selector: 'ng-zone-demo',
 template: `<h2>Demo: NgZone</h2>
 <p>Progress: {{progress}}</p>
 <p *ngIf="progress >= 100">Done processing {{label}} of Angular zone!</p>
 <button (click)="processWithinAngularZone()">Process within Angular zone</button>
 <button (click)="processOutsideOfAngularZone()">Process outside of Angular zone</button>
 `,
 export class NgZoneDemo {
 progress: number = 0;
 label: string;
 constructor(private _ngZone: NgZone) {}
 // Loop inside the Angular zone // so the UI DOES refresh after each setTimeout cycle
 processWithinAngularZone() {
 this.label = 'inside';
 this.progress = 0;
 this._increaseProgress(() => console.log('Inside Done!'));
 }
 // Loop outside of the Angular zone // so the UI DOES NOT refresh after each setTimeout cycle
 processOutsideOfAngularZone() {
 this.label = 'outside';
 this.progress = 0;
 this._ngZone.runOutsideAngular(() => {
 this._increaseProgress(() => {
 // reenter the Angular zone and display done
 this._ngZone.run(() => { console.log('Outside Done!'); });
 });
 });
 }
 _increaseProgress(doneCallback: () => void) {
 this.progress += 1;
 console.log(`Current progress: \${this.progress}%`);
 if (this.progress < 100) {
 window.setTimeout(() => this._increaseProgress(doneCallback), 10);
 } else {
 doneCallback();
 }
 }
 }
 }

```

asynchronous task when the application starts (for example for a polling process, started with a `setInterval`, a `setTimeout` or using RxJS operators like `interval`); - the `isStable` Observable runs outside of the Angular zone.

Let's imagine that you start a recurrent task (here incrementing a counter, using RxJS `interval`), and at the same time subscribe to `isStable`.

```

constructor(appRef: ApplicationRef) {
 appRef.isStable.pipe(
 filter(stable => stable)
).subscribe(() => console.log('App is stable now'));
 interval(1000).subscribe(counter => console.log(counter));
}

```

In this example, `isStable` will never emit `true` and the trace `"App is stable now"` will never get logged. If you want to execute something when the app is stable, you have to wait for the application to be stable before starting your polling process.

```

constructor(appRef: ApplicationRef) {
 appRef.isStable.pipe(
 first(stable => stable),
 tap(stable => console.log('App is stable now')),
 switchMap(() => interval(1000))
).subscribe(counter => console.log(counter));
}

```

In this example, the trace `"App is stable now"` will be logged and then the counter starts incrementing every second. Note also that this Observable runs outside of the Angular zone, which means that the code in the subscription to this Observable will not trigger the change detection.

Let's imagine that instead of logging the counter value, you update a field of your component and display it in its template.

```

constructor(appRef: ApplicationRef) {
 appRef.isStable.pipe(
 first(stable => stable),
 switchMap(() => interval(1000))
).subscribe(counter => this.value = counter);
}

```

As the `isStable` Observable runs outside the zone, the `value` field will be updated properly, but the template will not be refreshed! You'll have to manually trigger the change detection to update the template.

```

constructor(appRef: ApplicationRef, cd:
ChangeDetectorRef) {
 appRef.isStable.pipe(
 first(stable => stable),
 switchMap(() =>
interval(1000))
).subscribe(counter => {
 this.value = counter;
 cd.detectChanges();
 });
}

```

Or make the subscription callback run inside the zone.

```

constructor(appRef:
ApplicationRef, zone: NgZone) {
 appRef.isStable.pipe(
 first(stable => stable),
 switchMap(() =>
interval(1000))
).subscribe(counter => zone.run(() => this.value = counter));
}

```

```
