**Minimum amount of binding slots required in the runtime for style/class bindings.**  
 Styling in Angular uses up two slots in the runtime LView/TData data structures to record binding data, property information and metadata.  
 When a binding is registered it will place the following information in the LView:  
 slot 1) binding value  
 slot 2) cached value (all other values collected before it in string form)  
 When a binding is registered it will place the following information in the TData:  
 slot 1) prop name  
 slot 2) binding index that points to the previous style/class binding (and some extra config values)  
 Let's imagine we have a binding that looks like so:  

```

<div [style.width]="x" [style.height]="y">

```

 Our LView and TData data-structures look like so:  

```

typescript
LView = [
 // ...
 x, // value of x
 "width: x",
 y, // value of y
 "width: x; height: y",
 // ...
];
TData = [
 // ...
 "width", // binding slot 20
 0,
 "height",
 20,
 // ...
];

```

**A styling expression summary**

that is to be processed by the compiler

```

export interface StylingInstruction {
 reference:
 o.ExternalReference;
 /** Calls to individual styling instructions. Used when chaining calls to the same
 instruction. */
 calls: StylingInstructionCall[];
}
export interface StylingInstructionCall {
 sourceSpan:
 ParseSourceSpan|null;
 supportsInterpolation: boolean;
 allocateBindingSlots: number;
 params: ((convertFn:
 (value: any) => o.Expression | o.Expression[]) => o.Expression[]);
}

 value: AST;
}
/** Produces creation/update
 instructions for all styling bindings (class and style)
 * It also produces the creation instruction to register all
 initial styling values
 * (which are all the static class="..." and style="..." attribute values that exist
 * on an
 element within a template).
 * The builder class below handles producing instructions for the following cases:
 * - Static style/class attributes (style="..." and class="...")
 * - Dynamic style/class map bindings
 ([style]="map" and [class]="map|string")
 * - Dynamic style/class property bindings ([style.prop]="exp" and
 [class.name]="exp")
 * Due to the complex relationship of all of these cases, the instructions generated
 * for
 these attributes/properties/bindings must be done so in the correct order. The
 * order which these must be
 generated is as follows:
 * if (createMode) {
 * styling(...)
 * }
 * if (updateMode) {
 * styleMap(...)
 * classMap(...)
 * styleProp(...)
 * classProp(...)
 * }
 * The creation/update methods within the builder
 class produce these instructions.

/**
 * Error recovery should skip tokens until it encounters a recovery point. skip() treats the end of input and a ';' as unconditionally a recovery point. It also treats ')', '}' and ']' as conditional recovery points if one of calling productions is expecting one of these symbols. This allows skip() to recover from errors such as '(a.) + 1' allowing more of the AST to be retained (it doesn't skip any tokens as the ')' is retained because of the '(' begins an '(' <expr> ')' production). The recovery points of grouping symbols must be conditional as they must be skipped if none of the calling productions are not expecting the closing token else we will never make progress in the case of an extraneous group closing symbol (such as a stray ')'). This is not the case for ';' because parseChain() is always the root production and it expects a ';'. Furthermore, the presence of a stateful context can add more recovery points. - in a `Writable` context, we are able to recover after seeing the `=` operator, which signals the presence of an independent rvalue expression following the `=` operator.
 *
 * If a production expects one of these token it increments the corresponding nesting count, and then decrements it just prior to checking if the token is in the input.

Overview\n *\n * Each line represents one kind of element. The `element_inheritance` and properties are joined\n *
using `element_inheritance|properties` syntax.\n *\n * ## Element Inheritance\n *\n * The `element_inheritance` can
be further subdivided as `element1,element2,...^parentElement`.\n *\n * Here the individual elements are separated by
`,` (commas). Every element in the list\n * has identical properties.\n *\n * An `element` may inherit additional
properties from `parentElement` If no `^parentElement` is\n * specified then `""` (blank) element is assumed.\n *\n *
NOTE: The blank element inherits from root `[Element]` element, the super element of all\n * elements.\n *\n *
NOTE an element prefix such as `:svg:` has no special meaning to the schema.\n *\n * ## Properties\n *\n * Each
element has a set of properties separated by`,` (commas). Each property can be prefixed\n * by a special character
designating its type:\n *\n * - (no prefix): property is a string.\n * - `*`: property represents an event.\n * - `!`:
property is a boolean.\n * - `#`: property is a number.\n * - `%`: property is an object.\n *\n * ## Query\n *\n * The
class creates an internal squas representation which allows to easily answer the query of\n * if a given property exist
on a given element.\n *\n * NOTE: We don't yet support querying for types or events.\n * NOTE: This schema is
auto extracted from `schema_extractor.ts` located in the test folder,\n * see
dom_element_schema_registry_spec.ts\n */\n\n

out.join('');\n}\n\n/**\n * A regular expression for breaking a URI into its component parts.\n * \n * { @link
http://www.gbiv.com/protocols/uri/rfc/rfc3986.html#RFC2234 } says\n * As the \"first-match-wins\" algorithm is
identical to the \"greedy\" \n * disambiguation method used by POSIX regular expressions, it is natural and\n *
commonplace to use a regular expression for parsing the potential five\n * components of a URI reference.\n * \n *
The following line is the regular expression for breaking-down a\n * well-formed URI reference into its
components.\n * \n * <pre>\n * ^(([^:/?#]+):)?(//([^/?#]*))?(#[^#]*)?(\.(.*)?)?\n * 12 3 4 5
6 7 8 9\n * </pre>\n * \n * The numbers in the second line above are only to assist readability; they\n * indicate
the reference points for each subexpression (i.e., each paired\n * parenthesis). We refer to the value matched for
subexpression <n> as $<n>.\n * \n * For example, matching the above expression to\n * <pre>\n *
http://www.ics.uci.edu/pub/ietf/uri/#Related\n * </pre>\n * \n * results in the following subexpression matches:\n *
<pre>\n * $1 = http:\n * $2 = http\n * $3 = //www.ics.uci.edu\n * $4 = www.ics.uci.edu\n * $5 =
/pub/ietf/uri/\n * $6 = <undefined>\n * $7 = <undefined>\n * $8 = #Related\n * $9 = Related\n * </pre>\n *
where <undefined> indicates that the component is not present, as is the\n * case for the query component in the
above example. Therefore, we can\n * determine the value of the five components as\n * <pre>\n * scheme =
$2\n * authority = $4\n * path = $5\n * query = $7\n * fragment = $9\n * </pre>\n * \n * The regular
expression has been modified slightly to expose the\n * userInfo, domain, and port separately from the authority.\n *
The modified version yields\n * <pre>\n * $1 = http scheme\n * $2 = <undefined> userInfo -\\|\n *
$3 = www.ics.uci.edu domain | authority\n * $4 = <undefined> port -/\n * $5 = /pub/ietf/uri/ path\n *
$6 = <undefined> query without ?\n * $7 = Related fragment without #\n * </pre>\n * \n * @internal\n *
\nconst _splitRe = new RegExp(\n '^ +\n '(?: +\n '([^:/?#.]+' + // scheme - ignore special characters\n // used by other URL parts such as :,\n // ?, /, #, and .\n ')?' +\n '(?:/' +\n '([^/?#]*)@)?' +
 // userInfo\n '([\\w\\d\\-\\.\\u0100-\\uffff.%]*)' + // domain - restrict to letters,\n // digits, dashes, dots, percent\n // escapes, and unicode characters.\n '(?:([0-9]+))?' +
 // port\n ')?' +\n '([/?#]+)?' + // path\n '(?:\\|{([#]*)})?' + // query\n '(?:#(.*))?' + //
fragment\n '$');\n\n/**\n * The index of each URI component in the return value of goog.uri.utils.split.\n * \n * @enum

```

abstract class ASTWithName extends AST {
 constructor(span: ParseSpan, sourceSpan: AbsoluteSourceSpan, public nameSpan: AbsoluteSourceSpan)
 super(span, sourceSpan);
}
}

Represents a quoted expression of the form:
quote = prefix ` ` uninterpretedExpression
prefix = identifier
uninterpretedExpression = arbitrary string

A quoted expression is meant to be pre-processed by an AST transformer that converts it into another AST that no longer contains quoted expressions.
It is meant to allow third-party developers to extend Angular template expression language.
The `uninterpretedExpression` part of the quote is therefore not interpreted by the Angular's own expression parser.

export class Quote extends AST {
 constructor(span: ParseSpan, sourceSpan: AbsoluteSourceSpan, public prefix: string, public uninterpretedExpression: string, public location: any)
 super(span, sourceSpan);
}
visit(visitor: AstVisitor, context: any = null): any {

 // do nothing
 }
}

export class ImplicitReceiver extends AST {
 visit(visitor: AstVisitor, context: any = null): any {
 return visitor.visitImplicitReceiver(this, context);
 }
}

Receiver when something is accessed through `this` (e.g. `this.foo`). Note that this class inherits from `ImplicitReceiver`, because accessing something through `this` is treated the same as accessing it implicitly inside of an Angular template (e.g. `[attr.title]="this.title"` is the same as `[attr.title]="title"`). Inheriting allows for the `this` accesses to be treated the same as implicit ones, except for a couple of exceptions like `$event` and `$any`.
TODO: we should find a way for this class not to extend from `ImplicitReceiver` in the future.

export class ThisReceiver extends ImplicitReceiver {
 visit(visitor: AstVisitor, context: any = null): any {
 return visitor.visitThisReceiver?.(this, context);
 }
}

Multiple expressions separated by a semicolon.
